Recommended Production Architectures

v0.8 Details

Existing Core Functionality

- Basic Mongo database functionality: inserts, deletes, queries, indexing.
- Master / Slave Replication
- Replica Pairs
- Server-side javascript code execution

New to v0.8

- Drivers for Java, C++, Python, Ruby.
- db shell utility
- (Very) basic security
- $or
- Clean up logging
- Performance test baseline
- getlasterror
- Large capped collections
- Bug fixes (compound index keys, etc.)
- Import/Export utility
- Allow any _id that is unique, and verify uniqueness

Wanted, but may not make it

- AMI's
- Unlock eval()?
- Better disk full handling
- better replica pair negotiation logic (for robustness)

Building SpiderMonkey
Internals

Cursors

Tailable Cursors

See `p/db/dbclient.h` for example of how, on the client side, to support tailable cursors.

Set

```c
Option_CursorTailable = 2
```

in the `queryOptions` `int` field to indicate you want a tailable cursor.

If you get back no results when you query the cursor, keep the cursor live if `cursorid` is still nonzero. Then, you can issue future `getMore` requests for the cursor.

If a `getMore` request has the `resultFlag` `ResultFlag_CursorNotFound` set, the cursor is not longer valid. It should be marked as "dead" on the client side.

```c
ResultFlag_CursorNotFound = 1
```

See the `Queries and Cursors` section of the `Mongo Developers’ Guide` for more information about cursors.

See Also
The Queries and Cursors section of the Mongo Developers' Guide for more information about cursors

Mongo Concepts and Terminology

See the Manual page for information on the following:

- BSON
- Collections
- Cursors
- Databases
- Documents
- GridFS (for files and very large objects)
- Indexes
- Transactions / Atomic Operations

Replication Terms

- Replication. Duplicating data on multiple servers for HA, safety, disaster recovery, and a bit of scaling. Sharding and replication are used together.
- Member. A member (server) in a replica set.
- Primary. The replica set member that is currently "master" and receives all writes. Reads from the primary are "immediately consistent".
- Secondary. A replica set member that is currently not master and is applying operations it receives from the current primary.
- Arbiter. A replica set member that votes in elections of primary, but that has no data. Arbiters are very lightweight and can be used to break ties in elections. Add an arbiter if a set has an even number of members.
- Oplog. High level log of operations used by replication.

Sharding Terms

- Sharding. The partitioning / distribution of data among machines in a cluster. Each shard has different data. Sharding is the mechanism in MongoDB for building very large clusters. Note: we recommend you begin using MongoDB without sharding. It is easy to transition over to sharding later.
- Shard, Shard Key. See the sharding intro page.
- Chunk. A subset of documents in a collection that fit in a certain shard key range. See the sharding intro page.
- Config server. In a sharded environment, config servers store the metadata of the cluster. Each config server has a mongod process which stores metadata. Typically there are three config servers which have replicas of the same metadata (for data safety and HA). The config server mongod process is fairly lightweight and can be ran on machines performing other work. The config server data is very important be sure to include them in your backups of the cluster.
- mongod, mongos, mongo. MongoDB processes.

Other Concepts

- Durability / Journaling. Write-ahead logging for crash safety.
- Object IDs. Mongo documents include an _id field in each document.

Aggregation Framework - $limit

- Overview
- Specification
- Notes

Overview

The $limit pipeline operator limits the number of JSON documents that passes through it.

Specification

$limit takes a single numeric value as a parameter. Once that many documents have passed through the pipeline operator, no more will.

Here's a simple example:

```javascript
db.article.aggregate(
    { $limit : 5 }
);  
```

This pipeline will only pass through the first 5 documents that are seen. $limit has no effect on the content of the documents that are passed through – all fields present will be passed through as they are.

Notes

Aggregation Framework - $match

- Redirection Notice
  This page should redirect to http://docs.mongodb.org/manual/reference/aggregation/#_S_match.
Overview

$match filters documents. Documents which do not match the specified predicate are filtered out and do not progress further along the aggregation pipeline. Documents which do match are passed along unchanged.

Specification

$match predicate syntax is always exactly the same as that for queries; See Querying and Advanced Queries.

Within a pipeline, the $match operator appears thusly:

```javascript
db.article.aggregate(
    { $match : <match-predicate> }
);  
```

Here is an example with a simple field equality test:

```javascript
db.aggregate(
    { $match : { author : "dave" } }
);  
```

On its own like this, this is the equivalent of db.article.find({ author : "dave" }).

Here is another example, this time with a range test:

```javascript
db.article.aggregate(
    { $match : { score : { $gt : 50, $lte : 90 } } }
);  
```

Notes

$match should be placed as early in the aggregation pipeline as possible. This minimizes the number of documents after it, thereby minimizing later processing. Placing a $match at the very beginning of a pipeline will enable it to take advantage of indexes in exactly the same way as a regular query (find()/findOne()).

- Basic Guidelines
- Popular Topics
- Benefits of Submitting to our CFP
- Examples of Popular 2012 presentations
Where to Submit

We encourage people of all areas of experience submit proposals to our MongoDB days. MongoDB conferences draw a wide range of developers, sysadmins, DevOps professionals and data scientists from all levels of expertise, so we're looking for a variety of topics to cater to different audiences.

10gen Talk Proposal

Basic Guidelines

- The talk should be 30 minutes in length with 10 minutes for Q&A; your talk will be 40 minutes total
- Attendees are mostly developers, so gear your presentation towards a developer heavy audience
- Your talk should contain a 'message' or a 'theme' for attendees to take away
- Have fun with your topic! Each talk should be unique to the speaker giving it
- Have slides ready for review upon submission
- Feel free to email speakerinfo@10gen.com with questions.

Popular Topics

- Analytics
  - Using Hadoop
  - Using MongoDB Aggregation
- Optimizing Performance with MongoDB
- Gaming
- Data Modeling
- Deployment Architecture
- Migration Scenarios
- Hybrid Solutions
- Scaling MongoDB

FAQ

Q: Can I submit papers in my native language?
A: Yes, you can. We are interested in having native language presentations for conferences in our non-English speaking cities in order to make talks more accessible to our attendees

Q: My company is interested in sponsoring the conference. Can we sign up as sponsors and have a speaking slot?
A: Yes. We do not include speakings slots with sponsorship, but we accept proposals from everyone and are happy to have speakers, sponsors and attendees attend from one company. You can email sponsor@10gen.com for more information.

Q: I have not heard back yet. How do I know if my talk has been accepted?
A: If you have not heard back, we are still working on the content for the conference you submitted for. As soon as we make a definitive decision, you will hear from us. Feel free to contact speakerinfo@10gen.com if you have questions.

Benefits of Submitting to our CFP

- Every speaker who submits gets a free ticket to the conference
- Speaking at a MongoDB Conference is a great way to promote your product, your company, and yourself!
- MongoDB Conferences are highly valued as recruiting opportunities
- Being active in the MongoDB Community enables you to grow your presence in the open source community

Examples of Popular 2012 presentations

- Get Your Spatial On with MongoDB in the Cloud
- MongoDB Schema Design Insights and Tradeoffs
- Mongodb Versatility Scaling the MapMyFitness Platform
- Mapping Flatland Using MongoDB for an MMO Crossword Game

Conference Management Tools

Tools to Effectively Plan and Execute your Conference

- Planning
- Execution
- Manage Feedback
Planning

There are a few keys to effective planning materials. They should be easy to use, non-exclusive, and they should allow you to clone projects. Below are some tools we use for our conferences.

- **Mavenlink**
  - use Mavenlink as an overall project management system. Syncs with Google Apps.
- **Dropbox**
  - use Dropbox as a collaborative document store for your team
- **Jira**
  - use Jira as a project management system for contracts or colleagues who only own one item for your conferences, such as design and email campaigns
  - Google Apps
  - use google apps to create calendar invites for your speakers and staff, eliminating document loss and confusion
- **Fiesta.cc**
  - create mailing lists easily for your speakers, sponsors and staff.
- **Wiki Pages**
  - Create wiki pages for your speakers, sponsors and staff to communicate key information in a living document.
- **Eventbrite**
  - use eventbrite for registration and ticket sales. Eventbrite is easy to use with almost any CMS and has standard promotional templates for groups without the need for customizable options.
- **Twitter**
  - use twitter to promote your event and speakers, and on day of to tweet content in real time
- **Qrious**
  - use qrious to help your attendees network with each other, to autogenerate nametags with unique QRC (it syncs with eventbrite), and to provide your sponsors with leads.
- **[Guidebook]**
  - use guidebook for your mobile agenda and conference information needs

Execution

One drawback to planning conferences in multiple locations is that you often have no control over your environment, and limited knowledge of your resources until the day of the conference. Here are some ways to help keep your conference environment consistent:

- **Wifi Needs:**
  - Order wired lines
    - Presenters can use them and you can use them to connect a custom wireless network
  - **Meraki**
    - cloud managed wireless solutions put control of conference wifi in your hands
      - Tips:
        - Find out the conferences up bandwidth
        - Kill the conference's house wifi so you are not fighting with them
        - Get informed before you buy - Meraki has many different solutions for many different conferences
  - **Walkie Talkies**
    - These help your staff communicate immediately. Simple ones work for most environments. 
      - “Go” Bag:
        - Fill your “go” bag with these goodies and refresh immediately after a conference, and you will never be scrambling for sharps again!
          - scissors, tape, med kit, twine, extra stickie labels, pants, pens, sharpsies, batteries, usb keys, extra charges and extension cords, clickers and mini-display -> VGA adaptors
      - **Film Equipment** (try B&H for your needs!)
        - Record your speakers to add value to your website, or just to provide internal feedback, and avoid the cost of a film crew and the uncertainty that comes from having to use different film crews in different cities!
        - **We like:**
          - Sony HXR-MC50U Ultra Compact Pro AVCHD Camcorder
          - Sennheiser EW112-p G3 Camera Mount Wireless Microphone System with ME2
          - Lavalier Mic (G: 566-608MHz), Sony VCT-60AV Tripod with Remote in Grip
          - 
      - **Presentation Equipment:**
        - Buy 3 - 5 laptops to use at conferences, and load them with presentation software. This allows you to pre set hibernate settings, resolution etc and keeps speaker transitions smooth

Manage Feedback

Collection and managing feedback presents several difficulties. You want your feedback to be in depth, but you also want it to be low entry barrier, and you want your attendees to engage in feedback while it is fresh in their minds. Here are some tools we use.

- **Twitter**
  - Set up a twitter handle dedicated to your conferences. Ask people to tweet at you with feedback, and use DM to engage in dialogue. This creates a low entry barrier method of getting feedback with potential for more in depth conversation, and it prevents one negative comment (or even just a silly comment) from turning into spam on your #event twitter feed.
- **Guidebook**
Set up low entry barrier questions on guidebook with general multiple choice questions, and a link to your full survey

- [SurveyMonkey]
- Use survey monkey to create a conference survey that encompasses every talk, meal and any other aspect of your conference for complete feedback. Use giveaways to encourage participation

- JIRA
- Use JIRA to encourage and promote internal feedback. Your colleagues are probably passionate about your work and have a lot to say, but may feel intimidated by addressing you directly or even feel badly for providing criticism on something you’ve worked very hard on. Start general and get more specific based on what feedback you get the most!

Slide and Presentation Review
• Submitted your slides to speakerinfo@10gen.com.
  • An outline or partially finished content is totally fine; we just want to make sure we get you the feedback you need in a timely fashion. PowerPoint, KeyNote, Prezi, or PDF are all acceptable formats.
  • We are here to help! - we are happy to set up a session (Skype, hangout, call) to go through your presentation.

Equipment

Provided

• Projector, screen, and mic for speaker
• MacBook Mini Display port - VGA adaptor
• Wireless Clickers/Pointers - please do not take the USB adaptor with you on accident!

To Bring:

• A Laptop for your presentation
• A VGA adaptor for anything that is NOT a Mac mini display port
• Conference wifi is always unreliable so we recommend against any live demos that require Internet

Presentations

• Each presenter will have a 40 minute session time
• Please factor your Q&A time into this
• Each session has a short break between sessions to allow attendees to transition
• We have staff on hand to make sure you start and end on time.
• the session schedule can be viewed at

PresentationTips

Filming

We Are Filming You!

• Don’t wear stripes or busy print
• Do repeat questions from the audience before answering them.
• Do announce results if you poll the audience - such as “raise your hand if you use MongoDB”. Your next comments will much more relevant to viewers

Slide and Presentation Review

- Submitted your slides to speakerinfo@10gen.com.
- An outline or partially finished content is totally fine; we just want to make sure we get you the feedback you need in a timely fashion. PowerPoint, KeyNote, Prezi, or PDF are all acceptable formats.
- We are here to help! - we are happy to set up a session (Skype, hangout, call) to go through your presentation.

Equipment
**Provided**

- Projector, screen, and mic for speaker
- MacBook Mini Display port - VGA adaptor
- Wireless Clickers/Pointers - please do not take the USB adaptor with you on accident!

**To Bring:**

- A Laptop for your presentation
- A VGA adaptor for anything that is NOT a Mac mini display port
- Conference wifi is always unreliable so we recommend against any live demos that require Internet

**Presentations**

- Each presenter will have a 40 minute session time
- Please factor your Q&A time into this
- Each session has a short break between sessions to allow attendees to transition
- We have staff on hand to make sure you start and end on time.
- The session schedule can be viewed at

**Presentation Tips**

**Filming**

*We Are Filming You!*

- Don’t wear stripes or busy print
- Do repeat questions from the audience before answering them.
- Do announce results if you poll the audience - such as “raise your hand if you use MongoDB”. Your next comments will much more relevant to viewers

Slide and Presentation Review

- Submit your slides to speakerinfo@10gen.com.
  - An outline or partially finished content is totally fine; we just want to make sure we get you the feedback you need in a timely fashion. PowerPoint, KeyNote, Prezi, or PDF are all acceptable formats.
  - We are here to help! - we are happy to set up a session (Skype, hangout, call) to go through your presentation.

Equipment

Provided
- Projector, screen, and mic for speaker
- MacBook Mini Display port - VGA adaptor
- Wireless Clickers/Pointers - please do not take the USB adaptor with you on accident!

To Bring:
- A Laptop for your presentation
- A VGA adaptor for anything that is NOT a Mac mini display port
- Conference wifi is always unreliable so we recommend against any live demos that require Internet

Presentations

- Each presenter will have a 40 minute session time
- Please factor your Q&A time into this
- Each session has a short break between sessions to allow attendees to transition
- We have staff on hand to make sure you start and end on time.
- the session schedule can be viewed at

Presentation Tips

Filming
We Are Filming You!

- Don’t wear stripes or busy print
- Do repeat questions from the audience before answering them.
- Do announce results if you poll the audience - such as “raise your hand if you use MongoDB”. Your next comments will much more relevant to viewers

**Slide and Presentation Review**

- Submitted your slides to speakerinfo@10gen.com.
- An outline or partially finished content is totally fine; we just want to make sure we get you the feedback you need in a timely fashion. PowerPoint, KeyNote, Prezi, or PDF are all acceptable formats.
- We are here to help! - we are happy to set up a session (Skype, hangout, call) to go through your presentation.

**Equipment**

**Provided**

- Projector, screen, and mic for speaker
- MacBook Mini Display port - VGA adaptor
- Wireless Clickers/Pointers - please do not take the USB adaptor with you on accident!

**To Bring:**

- A Laptop for your presentation
- A VGA adaptor for anything that is NOT a Mac mini display port
- Conference wifi is always unreliable so we recommend against any live demos that require Internet

**Presentations**

- Each presenter will have a 40 minute session time
- Please factor your Q&A time into this
- Each session has a short break between sessions to allow attendees to transition
- We have staff on hand to make sure you start and end on time.
- The session schedule can be viewed at

**Presentation Tips**
Filming

We Are Filming You!

- Don’t wear stripes or busy print
- Do repeat questions from the audience before answering them.
- Do announce results if you poll the audience - such as “raise your hand if you use MongoDB”. Your next comments will much more relevant to viewers

Shipping Information

Detailed Shipping Information

Please ship as little as possible to the venue as there is very little holding space there. Arrange for it to arrive on Friday the 22nd or Monday the 25th between 10am and 6pm, as nobody will be there to receive the package outside of those hours.

Attention: Zacory Boatwright/10gen
Woolly Mammoth Theatre
641 D Street, NW
Washington, DC 20004

Please also be aware that we have no palette dolly. All shipments must be able to be broken up into smaller parts that may be moved by one person. Please keep in mind that our standard business hours (i.e. best times for delivery) would be Monday through Friday, 10 AM to 6 PM.

Presentation Tips

Slides

- Be precise in your slides - We will make them available on our website after the conference, so make sure they are correct and to the point.
- Be visual - a clever picture, easy to read chart, or even simple bullet points convey clear information.
- Use Big Font! the rooms are large and it is always hard to see from the back of the room
- Avoid including full text such as sentences and paragraphs in your slides.
- Know your audience - The audience is very technical, and generally knowledgeable about MongoDB.
- We will briefly introduce all of the sessions at the beginning of the event to give attendees an idea of what sessions their time would best be spent attending. Please familiarize yourself with the sessions as well.
- Turn off Hibernate! You don’t want your computer to go to sleep in the middle of your preso … or your audience might as well

Logistics

- Arrive 10 minutes early for your presentation; This gives everyone time to make sure that you and your equipment are ready to go! We will have a room monitor run through a check list to set you up.
- We will have a room monitor in each room, so if you need something, say something.
- Staging: Presenters in SkyTop, PennTop North and South, and the Madison will be presenting from a stage and podium. Presenters in Paris or London will be presenting from a podium.
- Projector and screen: You will be connecting with a Mac mini display adaptor to a VGA connection. If you need a different adaptor for your laptop, please bring it with you.
- Mic’s: A room monitor will equip with a lavaliar (clip on) when you arrive in your session room.
- Internet connectivity: Please do not rely on wifi for demos as we cannot guarantee it will work properly.
- Power: we will have power running to your podium. Please make sure your machine is fully charged anyway!

Questions

- If there is a microphone, make sure to wait for the person to get it, and use it.
- Repeat or rephrase the question to confirm it is what they are asking and everyone hears it.
- If the question is off-topic or lengthy, table it or ask the person to find you after the presentation.
- Move towards the person and away from the podium to engage the audience.
Introduction

MongoDB wasn’t designed in a lab. We built MongoDB from our own experiences building large scale, high availability, robust systems. We didn’t start from scratch, we really tried to figure out what was broken, and tackle that. So the way I think about MongoDB is that if you take MySql, and change the data model from relational to document based, you get a lot of great features: embedded docs for speed, manageability, agile development with schema-less databases, easier horizontal scalability
because joins aren’t as important. There are lots of things that work great in relational databases: indexes, dynamic queries and updates to name a few, and we haven’t changed much there. For example, the way you design your indexes in MongoDB should be exactly the way you do it in MySQL or Oracle, you just have the option of indexing an embedded field.

– Eliot Horowitz, 10gen CTO and Co-founder

Why MongoDB?

• Document-oriented
  • Documents (objects) map nicely to programming language data types
  • Embedded documents and arrays reduce need for joins
  • Dynamically-typed (schemaless) for easy schema evolution
  • No joins and no multi-document transactions for high performance and easy scalability

• High performance
  • No joins and embedding makes reads and writes fast
  • Indexes including indexing of keys from embedded documents and arrays
  • Optional streaming writes (no acknowledgements)

• High availability
  • Replicated servers with automatic master failover

• Easy scalability
  • Automatic sharding (auto-partitioning of data across servers)
    • Reads and writes are distributed over shards
  • No joins or multi-document transactions make distributed queries easy and fast
  • Eventually-consistent reads can be distributed over replicated servers

• Rich query language

Large MongoDB deployment

1. One or more shards, each shard holds a portion of the total data (managed automatically). Reads and writes are automatically routed to the appropriate shard(s). Each shard is backed by a replica set – which just holds the data for that shard.

A replica set is one or more servers, each holding copies of the same data. At any given time one is primary and the rest are secondaries. If the primary goes down one of the secondaries takes over automatically as primary. All writes and consistent reads go to the primary, and all eventually consistent reads are distributed amongst all the secondaries.

2. Multiple config servers, each one holds a copy of the meta data indicating which data lives on which shard.

3. One or more routers, each one acts as a server for one or more clients. Clients issue queries/uploads to a router and the router routes them to the appropriate shard while consulting the config servers.

4. One or more clients, each one is (part of) the user’s application and issues commands to a router via the mongo client library (driver) for its language.

`mongod` is the server program (data or config). `mongos` is the router program.
Small deployment (no partitioning)

1. One replica set (automatic failover), or one server with zero or more slaves (no automatic failover).

2. One or more clients issuing commands to the replica set as a whole or the single master (the driver will manage which server in the replica set to send to).

Mongo data model

- A Mongo system (see deployment above) holds a set of databases
- A database holds a set of collections
- A collection holds a set of documents
- A document is a set of fields
- A field is a key-value pair
- A key is a name (string)
- A value is a
  - basic type like string, integer, float, timestamp, binary, etc.,
  - a document, or
  - an array of values

Mongo query language

To retrieve certain documents from a db collection, you supply a query document containing the fields the desired documents should match. For example, `{name: {first: 'John', last: 'Doe'}}` will match all documents in the collection with name of John Doe. Likewise, `{name.last: 'Doe'}` will match all documents with last name of Doe. Also, `{name.last: /^D/}` will match all documents with last name starting with 'D' (regular expression match).

Queries will also match inside embedded arrays. For example, `{keywords: 'storage'}` will match all documents with 'storage' in its keywords array. Likewise, `{keywords: { $in: ['storage', 'DBMS']}}` will match all documents with 'storage' or 'DBMS' in its keywords array.

If you have lots of documents in a collection and you want to make a query fast then build an index for that query. For example, `ensureIndex({name.last: 1})` or `ensureIndex({keywords: 1})`. Note, indexes occupy space and slow down updates a bit, so use them only when the tradeoff is worth it.

2.2 Release Notes
Upgrading to 1.8

- Upgrading Replica Sets
- Upgrading Sharded Clusters
- Returning to 1.6
  - Journaling
- See Also
- Download

First, upgrade your shell (mongo) to the 1.8.x shell.

**Upgrading Replica Sets**

1.8.x secondaries can replicate from 1.6.x primaries.

1.6.x secondaries cannot replicate from 1.8.x primaries.

Thus, the trick is to replace all of your secondaries, then the primary.

For example, suppose we have a typical replica set with 1 primary, 1 secondary, and 1 arbiter. To upgrade this set, do the following:

1. For each arbiter:
   - Shut down the arbiter
   - Start it back up with the 1.8 binary
2. Change your config (optional)
   It is possible that, when you start shutting down members of the set, a new primary will be elected. If you wish to prevent this, you can give all of the slaves a priority of 0 before upgrading, then change them back afterwards.
   - Record your current config. Run `rs.conf()` and paste the results into a text file.
   - Update your config so that all secondaries have priority 0. For example:
For each slave:
- Shut down the slave
- Start it back up with the 1.8 binary
If you changed the config, change it back to its original state

Shut down the primary (the final 1.6 server) and restart it with the 1.8 binary.
**Upgrading Sharded Clusters**

1. Turn off the balancer:

   ```
   $ mongo <a_mongos_hostname>
   > use config
   > db.settings.update({_id:"balancer"},{$set : {stopped:true}})
   ```

2. For each shard:
   - If the shard is a replica set, follow the directions above for replica sets.
   - If the shard is a single mongod process, shut it down and start it back up with the 1.8 binary.

3. For each mongos:
   - Shut down the mongos process
   - Restart with the 1.8 binary

4. For each config server:
   - Shut down the config server process
   - Restart with the 1.8 binary

5. Turn on the balancer

   ```
   > use config
   > db.settings.update({_id:"balancer"},{$set : {stopped:false}})
   ```

**Returning to 1.6**

If something goes wrong and you wish to move back to 1.6, follow the steps above in reverse. Please be careful that you have not inserted any documents larger than 4MB while running on 1.8 (where the max size has increased to 16MB); if you have you will get errors when the server tries to read those documents.

**Journaling**

Returning to 1.6 after using 1.8 journaling works fine, as journaling does not change anything about the data file format. Suppose you are running 1.8 with journaling enabled and something isn't working for you, so you decide to switch back to 1.6. There are two scenarios:

1. If you shut down cleanly with 1.8.x, just restart with the 1.6 mongod binary.
2. If 1.8.x shut down uncleanly, start 1.8.x up again and let the journal files run to fix any damage (incomplete writes) that may have existed at the crash. Then shut down 1.8.0 cleanly and restart with the 1.6 mongod binary.

**See Also**

- [1.8 Release Notes](#) page for details on changes in v1.8 to map/reduce.

**Download**

- [Download v1.8](#)

**1.6 Release Notes**

MongoDB 1.6 is a drop-in replacement for 1.4. To upgrade, simply shutdown `mongod` then restart with the new binaries.*

* Please note that you should upgrade to the latest version of whichever driver you're using. Certain drivers, including the Ruby driver, will require the upgrade, and all the drivers will provide extra features for connecting to replica sets.

**Sharding**

Sharding is now production-ready, making MongoDB horizontally scalable, with no single point of failure. A single instance of `mongod` can now be upgraded to a distributed cluster with zero downtime when the need arises.

- Sharding Tutorial
- Sharding Documentation
- Upgrading a Single Server to a Cluster
Replica Sets

Replica sets, which provide automated failover among a cluster of n nodes, are also now available.

Please note that replica pairs are now deprecated; we strongly recommend that replica pair users upgrade to replica sets.

- Replica Set Tutorial
- Replica Set Documentation
- Upgrading Existing Setups to Replica Sets

Other Improvements

- The w option (and wtimeout) forces writes to be propagated to n servers before returning success (this works especially well with replica sets)
- $or queries
- Improved concurrency
- $slice operator for returning subsets of arrays
- 64 indexes per collection (formerly 40 indexes per collection)
- 64-bit integers can now be represented in the shell using NumberLong
- The findAndModify command now supports upserts. It also allows you to specify fields to return
- $showDiskLoc option to see disk location of a document
- Support for IPv6 and UNIX domain sockets

Installation

- Windows service improvements
- The C++ client is a separate tarball from the binaries

1.6.x Release Notes

- 1.6.5

1.5.x Release Notes

- 1.5.8
- 1.5.7
- 1.5.6
- 1.5.5
- 1.5.4
- 1.5.3
- 1.5.2
- 1.5.1
- 1.5.0

You can see a full list of all changes on Jira.

Thank you everyone for your support and suggestions!

1.4 Release Notes

We're pleased to announce the 1.4 release of MongoDB. 1.4 is a drop in replacement for 1.2. To upgrade you just need to shutdown mongod, then restart with the new binaries. (Users upgrading from release 1.0 should review the 1.2 release notes, in particular the instructions for upgrading the DB format.)

Release 1.4 includes the following improvements over release 1.2:

Core server enhancements

- concurrency improvements
- indexing memory improvements
- background index creation
- better detection of regular expressions so the index can be used in more cases

Replication & Sharding

- better handling for restarting slaves offline for a while
- fast new slaves from snapshots (--fastsync)
- configurable slave delay (--slavedelay)
- replication handles clock skew on master
- $inc replication fixes
- sharding alpha 3 - notably 2 phase commit on config servers

**Deployment & production**

- configure "slow threshold" for profiling
- ability to do fsync + lock for backing up raw files
- option for separate directory per db (--directoryperdb)
- [http://localhost:28017/_status](http://localhost:28017/_status) to get serverStatus via http
- REST interface is off by default for security (--rest to enable)
- can rotate logs with a db command, logRotate
- enhancements to serverStatus command (db.serverStatus()) - counters and replication lag stats
- new mongostat tool

**Query language improvements**

- $all with regex
- $not
- partial matching of array elements $elemMatch
- $ operator for updating arrays
- $addToSet
- $unset
- $pull supports object matching
- $set with array indices

**Geo**

- 2d geospatial search
- geo $center and $box searches

**1.2.x Release Notes**

**New Features**

- More indexes per collection
- Faster index creation
- Map/Reduce
- Stored JavaScript functions
- Configurable fsync time
- Several small features and fixes

**DB Upgrade Required**

There are some changes that will require doing an upgrade if your previous version is <= 1.0.x. If you're already using a version >= 1.1.x then these changes aren't required. There are 2 ways to do it:

- --upgrade
  - stop your mongod process
  - run ./mongod --upgrade
  - start mongod again
- use a slave
  - start a slave on a different port and data directory
  - when its synced, shut down the master, and start the new slave on the regular port.

Ask in the forums or IRC for more help.

**Replication Changes**

- There have been minor changes in replication. If you are upgrading a master/slave setup from <= 1.1.2 you have to update the slave first.

**mongoimport**

- mongoimportjson has been removed and is replaced with mongoimport that can do json/csv/tsv

**field filter changing**

- We've changed the semantics of the field filter a little bit. Previously only objects with those fields would be returned. Now the field filter
1.0 Changelist

Wrote MongoDB. See documentation.

Version Numbers

MongoDB uses the odd-numbered versions for development releases.

There are 3 numbers in a MongoDB version: A.B.C

- A is the major version. This will rarely change and signify very large changes
- B is the release number. This will include many changes including features and things that possible break backwards compatibility. Even Bs will be stable branches, and odd Bs will be development.
- C is the revision number and will be used for bugs and security issues.

For example:

- 1.0.0 : first GA release
- 1.0.x : bug fixes to 1.0.x - highly recommended to upgrade, very little risk
- 1.1.x : development release. this will include new features that are not fully finished, and works in progress. Some things may be different than 1.0
- 1.2.x : second GA release. this will be the culmination of the 1.1.x release.

What's New by Version

This is a summary of high level features only. See jira and release notes for full details.

1.4

- Geospatial
- Background indexing
- $directoryperdb
- Log rotate
- $not
- $ operator for updating arrays
- $addToSet
- $unset

1.6

- Sharding
- Replica Sets
- getLastError w param
- $or
- $slice
- 64 indexes per collection
- IPv6

1.8

- Journaling
- Sparse and covered indexes
- $rename
- mongos (i.e., sharded environment) will route SLAVE_OK queries to secondaries in replica sets

Drivers

MongoDB has client support for most programming languages. Download the driver for the language you are coding with for your application.

News: Introducing MongoClient

mongodb.org Supported
- C
- C++
- Erlang
- Haskell
- Java (and other JVM languages)
- Javascript
- .NET (C#, F#, PowerShell, ...)
- Node.js
- Perl
- PHP
- Python
- Ruby
- Scala

**Community Supported**

- ActionScript3
  - [http://www.mongoas3.com](http://www.mongoas3.com)
- C
  - libmongo-client
- C# and .NET
- Clojure

Hadoop

The MongoDB Hadoop Adapter is a plugin for Hadoop that provides Hadoop the ability to use MongoDB as an input source and/or an output source.

The source code is available on github where you can find a more comprehensive readme

If you have questions please email the mongodb-user Mailing List. For any issues please file a ticket in Jira.

Installation

The Mongo-Hadoop adapter uses the
SBT Build Tool tool for compilation. SBT provides superior support for discreet configurations targeting multiple Hadoop versions. The distribution includes a self-bootstrapping copy of SBT in the distribution as `sbt`. Create a copy of the jar files using the following command:

```
./sbt package
```

The MongoDB Hadoop Adapter supports a number of Hadoop releases. You can change the Hadoop version supported by the build by modifying the value of `hadoopRelease` in the `build.sbt` file. For instance, set this value to:

```
hadoopRelease in ThisBuild := "cdh3"
```

Configures a build against Cloudera CDH3u3, while:

```
hadoopRelease in ThisBuild := "0.21"
```

Configures a build against Hadoop 0.21 from the mainline Apache distribution.
After building, you will need to place the "core" jar and the "mongo-java-driver" in the "lib" directory of each Hadoop server.

For more complete install instructions please see the install instructions in the readme

Scala Language Center

Casbah: Casbah is the officially supported Scala driver for MongoDB. It provides wrappers and extensions to the Java driver meant to allow a more Scala-friendly interface to MongoDB. It supports serialization/deserialization of common Scala types (including collections and regex), Scala 2.8 collection versions of DBObject and DBList and a fluid query DSL.

- C# Driver LINQ Tutorial
- C# Driver Serialization Tutorial
- API Documentation
- C# Driver README
- Source Code

Several other C# drivers have been developed by the community. This is the "official" C# Driver supported by 10gen. It is similar in many ways to the various drivers that came before it, but it is not a direct replacement for any of them. Most people have found it easy to convert to using this driver, but you should expect to have to make some changes.

**Downloading the Driver**

The C# Driver is hosted at [github.com](https://github.com). Instructions for downloading the source code are at: Download Instructions

You can also download binary builds in either .msi or .zip formats from: http://github.com/mongodb/mongo-csharp-driver/downloads.

Note: if you download the .zip file Windows might require you to "Unblock" the help file. If Windows asks "Do you want to open this file?" when you double click on the CSharpDriverDocs.chm file, clear the check box next to "Always ask before opening this file" before pressing the Open button. Alternatively, you can right click on the CSharpDriverDocs.chm file and select Properties, and then press the Unblock button at the bottom of the General tab. If the Unblock button is not present then the help file does not need to be unblocked.

**Visual Studio Versions Supported**

The current version of the C# Driver has been built and tested using

- Visual Studio 2010
- Visual Studio 2008

**Questions and Bug Reports**

Questions about the C# driver (or any other MongoDB topic) can be posted at the mongodb-user Google Group:

[https://groups.google.com/group/mongodb-user](https://groups.google.com/group/mongodb-user)

Bug reports can be created in JIRA at:

[https://jira.mongodb.org/browse/CSHARP](https://jira.mongodb.org/browse/CSHARP)

  - OrderBy
Introduction

This tutorial covers the support for LINQ queries added in the 1.4 release of the C# driver.

You should already have read at least the quickstart introduction to the C# driver.

http://www.mongodb.org/display/DOCS/CSharp+Driver+Quickstart

Quickstart

First, add the following additional using statement to your program:

```csharp
using MongoDB.Driver.Linq;
```

Then, get a reference to a collection variable in the usual way:

```csharp
var collection = database.GetCollection<TDocument>("collectionname");
```

The basic idea behind writing a LINQ query is to start from a collection variable and begin the LINQ query by calling the AsQueryable<TDocument>() method. After that it's all standard LINQ.

For example:
You can also write queries using lambda syntax. The previous query would be written using lambda syntax like this:

```csharp
var query =
    collection.AsQueryable<Employee>()
    .Where(e => e.FirstName == "John")
    .Select(e => e);
```

The C# compiler translates all queries written using query syntax into lambda syntax internally anyway, so there is no performance advantage or penalty to choosing either style. You can also mix and match the styles, which can be useful when using query operators that are not supported by the query syntax.

All the code samples in this tutorial show both the query syntax and the lambda syntax for each query operator and supported where clauses.

Only LINQ queries that can be translated to an equivalent MongoDB query are supported. If you write a LINQ query that can’t be translated you will get a runtime exception and the error message will indicate which part of the query wasn’t supported.

**Note:** The 1.4 version of the C# driver requires that all where clauses that compare a field or property against a value have the constant on the right hand side. This restriction will be lifted in the next release.

### Supported LINQ query operators

#### Any

Without a predicate Any just tests whether the collection has any documents.

```csharp
result =
    (from c in collection.AsQueryable<C>()
     select c)
    .Any();
```

#### Any (with predicate)

With a predicate Any tests whether the collection has any matching documents.

```csharp
result =
    (from c in collection.AsQueryable<C>()
     select c)
    .Any(c => c.X == 1);`
result = (from c in collection.AsQueryable<C>() where c.X == 1 select c).Any();
// or
result = collection.AsQueryable<C>().Where(c => c.X == 1).Any();

Any with a predicate is not supported after a projection (at least not yet). So the following is not valid:

result = collection.AsQueryable<C>().Select(c => c.X).Any(x => x == 1);

You can usually rewrite such a query by putting an equivalent where clause before the projection (in which case you can drop the projection).

Count

Without a predicate Count just returns the number of documents in the collection.

result = (from c in collection.AsQueryable<C>() select c).Count();
// or
result = collection.AsQueryable<C>().Count();

Count (with predicate)

With a predicate Count returns the number of documents that match the predicate.

result = (from c in collection.AsQueryable<C>() select c).Count(c => c.X == 1);
// or
result = collection.AsQueryable<C>().Count(c => c.X == 1);

Note that the predicate can be provided either by a where clause or as an argument to Count, so the following are equivalent to the previous query.
var result =
(from c in collection.AsQueryable<C>()
 where c.X == 1
 select c)
 .Count();
// or
var result =
collection.AsQueryable<C>()
 .Where(c => c.X == 1)
 .Count();

Count with a predicate is not supported after a projection (at least not yet). So the following is not valid:

var result =
collection.AsQueryable<C>()
 .Select(c => c.X)
 .Count(x => x == 1);

You can usually rewrite such a query by putting an equivalent where clause before the projection (in which case you can drop the projection).

**Distinct**

Distinct returns the unique values of a field or property of the documents in the collection. You use a projection to identify the field or property whose distinct values you want.

var result =
(from c in collection.AsQueryable<C>()
 select c.X)
 .Distinct();
// or
var result =
collection.AsQueryable<C>()
 .Select(c => c.X)
 .Distinct();

The projection must select a particular field or property of the document. If the value of that field or property is represented in MongoDB as an array you can also use array indexing to select an item from the array.

var result =
(from c in collection.AsQueryable<C>()
 select c.A[i])
 .Distinct();
// or
var result =
collection.AsQueryable<C>()
 .Select(c => c.A[i])
 .Distinct();

**ElementAt**

ElementAt returns a particular document from a result set. Often you will combine this with a sort order.
result =
(from c in collection.AsQueryable<C>()
where c.X > 0
orderby c.X
select c)
// or
result =
collection.AsQueryable<C>()
.Where(c => c.X > 0)
.OrderBy(c => c.X)
.ElementAt(index);

If the result set has fewer documents than index ElementAt throws an exception.

**ElementAtOrDefault**

ElementAtOrDefault is just like ElementAt except that if there are fewer documents than index it returns null instead of throwing an exception.

**First**

First returns the first document from a result set. Often you will combine this with a sort order.

result =
(from c in collection.AsQueryable<C>()
where c.X > 0
orderby c.X
select c)
// or
result =
collection.AsQueryable<C>()
.where(c => c.X > 0)
.OrderBy(c => c.X)
.First();

If the result set has no documents First throws an exception.

**First (with predicate)**

This overload of First allows you to provide a predicate as an argument to First. This is an alternative to using a where clause.

result =
(from c in collection.AsQueryable<C>()
orderby c.X
select c)
// or
result =
collection.AsQueryable<C>()
.OrderBy(c => c.X)
.First(c => c.X > 0);

First with a predicate is not supported after a projection (at least not yet). So the following is not valid:
result = var collection.AsQueryable<C>()
    .OrderBy(c => c.X)
    .Select(c => c.X)
    .Count(x => x > 0);

You can usually rewrite such a query by putting an equivalent where clause before the projection.

If the result set has no documents First with a predicate throws an exception.

FirstOrDefault

FirstOrDefault is just like First except that if there are no matching documents it returns null instead of throwing an exception.

FirstOrDefault (with predicate)

FirstOrDefault with a predicate is just like First with a predicate except that if there are no matching documents it returns null instead of throwing an exception.

Last

Last returns the last document from a result set. Often you will combine this with a sort order.

result = var (from c in collection.AsQueryable<C>()
    where c.X > 0
    orderby c.X
    select c)
    .Last();

// or
result = var collection.AsQueryable<C>()
    .Where(c => c.X > 0)
    .OrderBy(c => c.X)
    .Last();

If the result set has no documents Last throws an exception.

Last (with predicate)

This overload of Last allows you to provide a predicate as an argument to Last. This is an alternative to using a where clause.

result = var (from c in collection.AsQueryable<C>()
    orderby c.X
    select c)
    .Last(c => c.X > 0);

// or
result = var collection.AsQueryable<C>()
    .OrderBy(c => c.X)
    .Last(c => c.X > 0);

Last with a predicate is not supported after a projection (at least not yet). So the following is not valid:
var result =
    collection.AsQueryable<C>().
    .OrderBy(c => c.X)
    .Select(c => c.X)
    .Last(x => x > 0);

You can usually rewrite such a query by putting an equivalent where clause before the projection.

If the result set has no documents Last throws an exception.

**LastOrDefault**

LastOrDefault is just like Last except that if there are no matching documents it returns null instead of throwing an exception.

**LastOrDefault (with predicate)**

LastOrDefault with a predicate is just like Last with a predicate except that if there are no matching documents it returns null instead of throwing an exception.

**LongCount**

LongCount is just like Count except that the return value is a 64-bit integer instead of a 32-bit integer.

**LongCount (with predicate)**

LongCount with a predicate is just like Count with a predicate except that the return value is a 64-bit integer instead of a 32-bit integer.

**Max**

Max returns the maximum value of a field or property of the documents in the collection. You use a projection to identify the field or property whose maximum value you want.

```
var result =
    (from c in collection.AsQueryable<C>()
     select c.X)
    .Max();
    // or
    result =
    collection.AsQueryable<C>()
    .Select(c => c.X)
    .Max();
```

The projection must select a particular field or property of the document. If the value of that field or property is represented in MongoDB as an array you can also use array indexing to select an item from the array.

```
var result =
    (from c in collection.AsQueryable<C>()
     select c.A[i])
    .Max();
    // or
var result =
    collection.AsQueryable<C>()
    .Select(c => c.A[i])
    .Max();
```

**Max (with selector)**

This overload of Max lets you select the field or property whose maximum value you want as an argument to Max instead of to Select.
Min

Min returns the minimum value of a field or property of the documents in the collection. You use a projection to identify the field or property whose minimum value you want.

\[
\text{var result} = \\
\quad \text{(from } \text{c in collection.AsQueryable\text{<C>()}} \\
\quad \quad \text{select c.X)} \\
\quad \text{.Min();} \\
\quad // \text{ or} \\
\text{var result} = \\
\quad \text{collection.AsQueryable\text{<C>()}} \\
\quad \quad \text{.Select(c => c.X)} \\
\quad \text{.Min();}
\]

The projection must select a particular field or property of the document. If the value of that field or property is represented in MongoDB as an array you can also use array indexing to select an item from the array.

\[
\text{var result} = \\
\quad \text{(from } \text{c in collection.AsQueryable\text{<C>()}} \\
\quad \quad \text{select c.A[i]}) \\
\quad \text{.Min();} \\
\quad // \text{ or} \\
\text{var result} = \\
\quad \text{collection.AsQueryable\text{<C>()}} \\
\quad \quad \text{.Select(c => c.A[i])} \\
\quad \text{.Min();}
\]

Min (with selector)

This overload of Min lets you select the field or property whose minimum value you want as an argument to Min instead of Select.

\[
\text{var result} = \\
\quad \text{(from } \text{c in collection.AsQueryable\text{<C>()}} \\
\quad \quad \text{select c)} \\
\quad \text{.Min(c => c.X));} \\
\quad // \text{ or} \\
\text{var result} = \\
\quad \text{collection.AsQueryable\text{<C>()}} \\
\quad \quad \text{.Min(c => c.X);}
\]

OrderBy

OrderBy is used to specify an ascending sort order for the result set.
```csharp
var query =
    from c in collection.AsQueryable<C>()
    orderby c.X
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .OrderBy(c => c.X);

OrderByDescending

OrderBy is used to specify a descending sort order for the result set.

```csharp
var query =
    from c in collection.AsQueryable<C>()
    orderby c.X descending
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .OrderByDescending(c => c.X);
```

Select

Select is used to project a new result type from the matching documents. In the 1.4 version of the C# driver a projection must typically be the last operation (with a few exceptions like Distinct, Max and Min).

```csharp
var query =
    from c in collection.AsQueryable<C>()
    select new { c.X, c.Y };
// or
var query =
    collection.AsQueryable<C>()
    .Select(c => new { c.X, c.Y });
```

Single

Single returns the first and only document from a result set.

```csharp
var result =
    (from c in collection.AsQueryable<C>()
     where c.X > 0
     orderby c.X
     select c)
    .Single();
// or
var result =
    collection.AsQueryable<C>()
    .Where(c => c.X > 0)
    .OrderBy(c => c.X)
    .Single();
```

If the result set has no documents or multiple documents Single throws an exception.

Single (with predicate)

This overload of Single allows you to provide a predicate as an argument to Single. This is an alternative to using a where clause.
result = 
(from c in collection.AsQueryable<C>()
orderby c.X
select c)
.Single(c => c.X > 0);
// or
var result =
collection.AsQueryable<C>()
.OrderBy(c => c.X)
.Single(c => c.X > 0);

Single with a predicate is not supported after a projection (at least not yet). So the following is not valid:

var result =
collection.AsQueryable<C>()
.OrderBy(c => c.X)
.Select(c => c.X)
.Single(x => x > 0);

You can usually rewrite such a query by putting an equivalent where clause before the projection.

If the result set has no documents or multiple documents Single throws an exception.

SingleOrDefault

SingleOrDefault is just like Single except that if there are no matching documents it returns null instead of throwing an exception.

SingleOrDefault (with predicate)

SingleOrDefault with a predicate is just like Single with a predicate except that if there are no matching documents it returns null instead of throwing an exception.

Skip

Use Skip to specify how many documents to skip from the beginning of the result set. Often you will combine Skip with a sort order.

var query =
(from c in collection.AsQueryable<C>()
orderby c.X
select c)
.Skip(100);
// or
var query =
collection.AsQueryable<C>()
.OrderBy(c => c.X)
.Skip(100);

Take

Use Take to specify how many documents to return from the server. When combining Take with Skip often you will also specify a sort order.
ThenBy

ThenBy is used to specify an additional ascending sort order for the result set.

```csharp
var query =
(from c in collection.AsQueryable<C>()
 orderby c.X, c.Y
 select c;
// or
var query =
 collection.AsQueryable<C>()
 .OrderBy(c => c.X)
 .ThenBy(c => c.Y);
```

ThenByDescending

ThenBy is used to specify an additional descending sort order for the result set.

```csharp
var query =
(from c in collection.AsQueryable<C>()
 orderby c.X, c.Y descending
 select c;
// or
var query =
 collection.AsQueryable<C>()
 .OrderBy(c => c.X)
 .ThenByDescending(c => c.Y);
```

Where

A where clause is used to specify which documents the query should return. A where clause is a C# expression that maps the query document type to a boolean value. If the expression returns true the document "matches" the query and is included in the result set.

```csharp
var query =
(from c in collection.AsQueryable<C>()
 where c.X > 0
 where c.X > 0
 select c;
// or
var query =
 collection.AsQueryable<C>()
 .Where(c => c.X > 0);
```

Sometimes a predicate can be supplied in other places besides a where clause, and it is also possible to have multiple where clauses. When multiple predicates are involved they are combined into a single composite predicate by combining the individual predicates with the && operator.

For example, the following queries are equivalent:
**Supported where clauses**

This section documents the supported where clauses.

As mentioned earlier, not all C# expressions are supported as a where clause. You can use this documentation as a guide to what is supported, or you can just try an expression and see if it works (a runtime exception is thrown if the where clause is not supported).

Where clauses are typically introduced using the Where query operator, but the same expressions are supported wherever a predicate is called for. In some cases multiple where clauses and predicates will be combined, in which case they are combined with the && operator.

**Note:** The 1.4 version of the C# driver requires that all where clauses that compare a field or property against a value have the constant on the right hand side. This restriction will be lifted in the next release.

**And (&& operator)**

Sub-expressions can be combined with the && operator to test whether all of them are true.

```csharp
var query = 
    (from c in collection.AsQueryable<C>()
     where c.X > 0 && c.Y > 0
     select c);
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => c.X > 0 && c.Y > 0);
```

This is translated to the following MongoDB query:

```
{ X : { $gt : 0 }, Y : { $gt : 0 } }
```

In some cases the And query can’t be flattened as shown, and the $and operator will be used. The following example matches documents where X is both a multiple of 2 and a multiple of 3:

```csharp
var query = 
    (from c in collection.AsQueryable<C>()
     where (c.X % 2 == 0) && (c.X % 3 == 0)
     select c);
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => (c.X % 2 == 0) && (c.X % 3 == 0));
```

This is translated to the following MongoDB query using $and:

```
{ $and : [{ X : { $mod : [2, 0] } }, { X : { $mod : [3, 0] } }] }
```
Any

This method is used to test whether an array field or property contains any items.

```csharp
var query =
    from c in collection.AsQueryable<C>()
    where c.A.Any()
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => c.A.Any());
```
matches any document where A has 1 or more items.

This is translated to the following MongoDB query:

```
{ A : { $ne : null, $not : { $size : 0 } } }
```

Boolean constant

This form is mostly for completeness. You will probably use it rarely. It allows a boolean constant to be used to either match or not match the document.

```csharp
var query =
    from c in collection.AsQueryable<C>()
    where true
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => true);
```

This is translated to the following MongoDB query:

```
{ _id : { $exists : true } }
```

Which matches all documents since the _id is a mandatory field.

Boolean field or property

A boolean field or property of the document doesn't have to be compared to true, it can just be mentioned in the where clause and there is an implied comparison to true.

```csharp
var query =
    from c in collection.AsQueryable<C>()
    where c.B
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => c.B);
```

This is translated to the following MongoDB query:
Contains (Enumerable method)

This method is used to test whether an array (or array-like) field or property contains a particular value:

```csharp
var query =
    from c in collection.AsQueryable<C>()
    where c.A.Contains(123)
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => c.A.Contains(123));
```

This is translated to the following MongoDB query:

```
{ A : 123 }
```

This translation relies on the way array fields are treated by the MongoDB query language.

Contains (string method)

This method is used to test whether a string field or property of the document contains a particular substring:

```csharp
var query =
    from c in collection.AsQueryable<C>()
    where c.S.Contains("abc")
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => c.S.Contains("abc"));
```

This is translated to the following MongoDB query (using regular expressions):

```
{ S : /abc/ }
```

ContainsAll (LINQ to MongoDB extension method)

This method is used to test whether an array (or array-like) field or property contains all of the provided values:

```csharp
var query =
    from c in collection.AsQueryable<C>()
    where c.A.ContainsAll(new[] { 1, 2, 3 })
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => c.A.ContainsAll(new[] { 1, 2, 3 }));
```

This is translated to the following MongoDB query:
ContainsAny (LINQ to MongoDB extension method)

This method is used to test whether an array (or array-like) field or property contains any of the provided values.

```csharp
var query =
    from c in collection.AsQueryable<C>()
    where c.A.ContainsAny(new[] { 1, 2, 3 })
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => c.A.ContainsAny(new[] { 1, 2, 3 }));
```

This is translated to the following MongoDB query:

```
( A : { $in : [1, 2, 3] } )
```

Count method (array length)

This method is used to test whether an enumerable field or property has a certain count of items.

```csharp
var query =
    from c in collection.AsQueryable<C>()
    where c.L.Count() == 3
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => c.L.Count() == 3);
```

This is translated to the following MongoDB query:

```
( L : { $size: 3 } )
```

Count property (array length)

This property is used to test whether a list (or list-like) field or property has a certain count of items.

```csharp
var query =
    from c in collection.AsQueryable<C>()
    where c.L.Count == 3
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => c.L.Count == 3);
```

This is translated to the following MongoDB query:

```
( L : { $size: 3 } )
```
EndsWith (string method)

This method is used to test whether a string field or property of the document ends with a particular substring.

```csharp
var query =
    from c in collection.AsQueryable<C>()
    where c.S.EndsWith("abc")
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => c.S.EndsWith("abc"));
```

This is translated to the following MongoDB query (using regular expressions):

```
{ S : /abc$/ }
```

Enum comparisons (==, !=, <, <=, >, >=)

Enum fields or properties can be compared to constants of the same enum type. The relative comparison are based on the value of the underlying integer type.

```csharp
public enum E { None, A, B };

var query =
    from c in collection.AsQueryable<C>()
    where c.E == E.A
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => c.E == E.A);
```

This is translated to the following MongoDB query:

```
{ E : 1 }
```

The LINQ implementation takes the representation of serialized values into account, so if you have configured your class map to store enums as string values instead of integer values the MongoDB query would instead be:

```
{ E : "A" }
```

In (LINQ to MongoDB extension method)

The In method is used to test whether a field or property is equal any of a set of provided values.
var query = 
  from c in collection.AsQueryable<C>()
  where c.X.In(new [] { 1, 2, 3 })
  select c;
// or
var query = 
  collection.AsQueryable<C>()
  .Where(c.X.In(new [] { 1, 2, 3 }));

This is translated to the following MongoDB query:

{ X : { $in : [1, 2, 3] } }

Inject

Inject is a pseudo-method that is used to inject a lower level MongoDB query into a LINQ query. The following query looks for X values that are larger than 0 and are 64-bit integers.

var query = 
  from c in collection.AsQueryable<C>()
  where c.X > 0 && Query.Type("X", BsonType.Int64).Inject()
  select c;
// or
var query = 
  collection.AsQueryable<C>()
  .Where(c => c.X > 0 && Query.Type("X", BsonType.Int64).Inject());

This is translated to the following MongoDB query:

{ X : { $gt : 0, $type : 18 } }

IsMatch (regular expression method)

This method is used to test whether a string field or property matches a regular expression.

var regex = new Regex("^abc");
var query = 
  from c in collection.AsQueryable<C>()
  where regex.IsMatch(c.S)
  select c;
// or
var query = 
  collection.AsQueryable<C>()
  .Where(c => regex.IsMatch(c.S));

This is translated to the following MongoDB query:

{ S : /^abc/ }

You can also use the static IsMatch method.
var query =
    from c in collection.AsQueryable<C>()
    where Regex.IsMatch(c.S, "^abc")
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => Regex.IsMatch(c.S, "^abc"));

This is translated to the following MongoDB query:

{ S : /^abc/ }

Length (array length)

This method is used to test whether an array (or array-like) field or property has a certain count of items.

var query =
    from c in collection.AsQueryable<C>()
    where c.A.Length == 3
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => c.A.Length == 3);

This is translated to the following MongoDB query:

{ A : { $size: 3 } }

Mod (% operator)

This operator is used to test the result of the mod operator against a field or property of the document. The following query matches all the documents where \(X\) is odd.

var query =
    from c in collection.AsQueryable<C>()
    where c.X % 2 == 1
    select c;
// or
var query =
    collection.AsQueryable<C>()
    .Where(c => c.X % 2 == 1);

This is translated to the following MongoDB query:

{ X : { $mod : [2, 1] } }

Not (! operator)

The ! operator is used to reverse the sense of a test.
This is translated into the following MongoDB query:

```
{ X : { $not : { $gt : 1 } } }
```

Note that !(c.X > 1) is not equivalent to (c.X <= 1) in cases where c.X is missing or does not have a numeric type.

**Numeric comparisons (==, !=, <, <=, >, >=)**

Numeric fields or properties can be compared using any of the above operators.

This is translated into the following MongoDB query:

```
{ X : 0, Y : { $lt : 100 } }
```

**Or (|| operator)**

Sub-expressions can be combined with the || operator to test whether any of them is true.

This is translated to the following MongoDB query:

```
{ $or : [{ X : { $gt : 0 } }, { Y : { $gt : 0 } }] }
```

**StartsWith (string method)**

This method is used to test whether a string field or property of the document starts with a particular substring.
This is translated to the following MongoDB query (using regular expressions):

```csharp
{ S : /^abc/ }
```

**CSharp Driver Quickstart**

- Introduction
- Downloading the C# driver
- Add a reference to the C# driver DLLs
- Add required using statements
- Get a reference to the client object
- Get a reference to a server object
- Get a reference to a database object
- Decide if you want to work with the BsonDocument object model or with your own domain classes
- Get a reference to a collection object
- Insert a document
- Find an existing document
- Save a document
- Update an existing document
- Remove an existing document
- You do NOT need to call Connect or Disconnect
- Full sample program

**Introduction**

This quick-start provides just enough information to get you started using the C# driver. After you have gotten started you can refer to the rest of the documentation for more information.

**Downloading the C# driver**

You can download the C# driver here:

http://github.com/mongodb/mongo-csharp-driver/downloads

If you downloaded the .zip file, simply unzip it and place the contents anywhere you want.

If you downloaded the .msi file, double click on the .msi file to run the setup program, which will install the C# driver DLLs in the "C:\Program Files (x86)\MongoDB\CSharp Driver 1.x" directory (the exact path may vary on your system).

**Add a reference to the C# driver DLLs**

Right click on the References folder in Visual Studio's Solution Explorer and select "Add Reference...". Navigate to the folder where the C# driver DLLs were installed and add a reference to the following DLLs:

1. MongoDB.Bson.dll
2. MongoDB.Driver.dll

As an alternative you could use the NuGet package manager to add the C# driver package to your solution.

**Add required using statements**

As a minimum you will need the following using statements:
using MongoDB.Bson;
using MongoDB.Driver;

Additionally, you will frequently add one or more of these using statements:

using MongoDB.Driver.Builders;
using MongoDB.Driver.GridFS;
using MongoDB.Driver.Linq;

There are additional namespaces that would only be required in special cases.

Get a reference to the client object

The easiest way to get a reference to a client object is using a connection string:

```csharp
var connectionString = "mongodb://localhost";
var client = new MongoClient(connectionString);
```

If you want to store the client object in a global variable you can. MongoClient is thread-safe.

Get a reference to a server object

To get a reference to a server object from the client object, write this:

```csharp
var server = client.GetServer();
```

Get a reference to a database object

To get a reference to a database object from the server object, write this:

```csharp
var database = server.GetDatabase("test"); // "test" is the name of the database
```

If you use more than one database call GetDatabase again for each database you want to use.

Decide if you want to work with the BsonDocument object model or with your own domain classes

There are two ways you can work with collections:

1. using the BsonDocument object model
2. using your own domain classes

You would use the BsonDocument object model when the data you are working with is so free form that it would be difficult or impossible to define domain classes for it.

Because it is so much easier to work with your own domain classes this quick-start will assume that you are going to do that. The C# driver can work with your domain classes provided that they:

1. Have a no-argument constructor
2. Define public read/write fields or properties for the data you want stored in the database

These requirements are essentially the same as those imposed by .NET's XmlSerializer.

In addition, if your domain class is going to be used as the root document it must contain an Id field or property (typically named "Id" although you can override that if necessary). Normally the Id will be of type ObjectId.

Get a reference to a collection object
For purposes of illustration let's assume you are using a domain class called Entity. You would get a reference to a collection containing Entity documents like this:

```csharp
var collection = database.GetCollection<Entity>("entities"); // "entities" is the name of the collection
```

### Insert a document

Inserting a document is easy:

```csharp
var entity = new Entity { Name = "Tom" };
collection.Insert(entity);
var id = entity.Id; // Insert will set the Id if necessary (as it was in this example)
```

### Find an existing document

In this example we will read back an Entity assuming we know the Id value:

```csharp
var query = Query.EQ(">id", id);
var entity = collection.FindOne(query);
```

Query.EQ is using the Query builder class to help you build the query. ".id" is the name of the field as stored in the database (normally the name of the field in the database is exactly the same as the name of the field or property in your domain class, but Id is an exception and is mapped to ".id" in the database).

Other query operators include: GT, GTE, In, LT, LTE, Near, NE, And, Or (and a few other more specialized ones).

### Save a document

You can save changes to an existing document like this:

```csharp
entity.Name = "Dick";
collection.Save(entity);
```

### Update an existing document

An alternative to Save is Update. The difference is that Save sends the entire document back to the server, but Update sends just the changes. For example:

```csharp
var query = Query.EQ("_id", id);
var update = Update.Set("Name", "Harry"); // update modifiers
collection.Update(query, update);
```

This example uses the Update builder to easily build the update modifiers.

### Remove an existing document

To remove an existing document from a collection you write:

```csharp
var query = Query.EQ("_id", id);
collection.Remove(query);
```

You do NOT need to call Connect or Disconnect
The C# driver has a connection pool to use connections to the server efficiently. There is no need to call Connect or Disconnect; just let the driver take care of the connections (calling Connect is harmless, but calling Disconnect is bad because it closes all the connections in the connection pool).

### Full sample program

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using MongoDB.Bson;
using MongoDB.Driver;
using MongoDB.Driver.Builders;

namespace ConsoleApplication1
{
    public class Entity
    {
        public ObjectId Id { get; set; }
        public string Name { get; set; }
    }

    class Program
    {
        static void Main(string[] args)
        {
            var connectionString = "mongodb://localhost";
            var client = new MongoClient(connectionString);
            var server = client.GetServer();
            var database = server.GetDatabase("test");
            var collection = database.GetCollection<Entity>("entities");

            var entity = new Entity { Name = "Tom" };
            collection.Insert(entity);
            var id = entity.Id;

            var query = Query.EQ("_id", id);
            entity = collection.FindOne(query);

            entity.Name = "Dick";
            collection.Save(entity);

            var update = Update.Set("Name", "Harry");
            collection.Update(query, update);
            collection.Remove(query);
        }
    }
}
```

### CSharp Driver Serialization Tutorial

- **Introduction**
- **Creating a class map**
- **Conventions**
- **Field or property level serialization options**
  - Opt-In
  - Element name
  - Element order
  - Identifying the Id field or property
  - Selecting an IdGenerator to use for an Id field or property
  - Ignoring a field or property
  - Ignoring null values
  - Default values
  - Ignoring a member based on a ShouldSerializeXyz method
Introduction

This document refers to version 1.6 of the C# Driver.

This section of the C# Driver Tutorial discusses serialization (and deserialization) of instances of C# classes to and from BSON documents. Serialization is the process of mapping an object to a BSON document that can be saved in MongoDB, and deserialization is the reverse process of reconstructing an object from a BSON document. For that reason the serialization process is also often referred to as "Object Mapping."

Serialization is handled by the BSON Library. The BSON Library has an extensible serialization architecture, so if you need to take control of serialization you can. The BSON Library provides a default serializer which should meet most of your needs, and you can supplement the default serializer in various ways to handle your particular needs.

The main way the default serializer handles serialization is through "class maps". A class map is a structure that defines the mapping between a class and a BSON document. It contains a list of the fields and properties of the class that participate in serialization and for each one defines the required serialization parameters (e.g., the name of the BSON element, representation options, etc...).

The default serializer also has built in support for many .NET data types (primitive values, arrays, lists, dictionaries, etc...) for which class maps are not used.

Before an instance of a class can be serialized a class map must exist. You can either create this class map yourself or simply allow the class map to be created automatically when first needed (called "automapping"). You can exert some control over the automapping process either by decorating your classes with serialization related attributes or by using initialization code (attributes are very convenient to use but for those who prefer to keep serialization details out of their domain classes be assured that anything that can be done with attributes can also be done without them).

Creating a class map

To create a class map in your initialization code write:

```csharp
BsonClassMap.RegisterClassMap<MyClass>();
```

which results in MyClass being automapped and registered. In this case you could just as well have allowed the class to be automapped by the serializer (when first serialized or deserialized). The one case where you must call RegisterClassMap yourself (even without arguments) is when you are using a polymorphic class hierarchy: in this case you must register all the known subclasses to guarantee that the discriminators get registered.

If you want to control the creation of the class map you can provide your own initialization code in the form of a lambda expression:

```csharp
BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.MapProperty(c => c.SomeProperty);
    cm.MapProperty(c => c.AnotherProperty);
});
```
When your lambda expression is executed the cm (short for class map) parameter is passed an empty class map for you to fill in. In this example two properties are added to the class map by calling the MapProperty method. The arguments to MapProperty are themselves lambda expressions which identify the property of the class. The advantage of using a lambda expression instead of just a string parameter with the name of the property is that Intellisense and compile time checking ensure that you can't misspell the name of the property.

It is also possible to use automapping and then override some of the results. We will see examples of that later on.

Note that a class map must only be registered once (an exception will be thrown if you try to register the same class map more than once). Usually you call RegisterClassMap from some code path that is known to execute only once (the Main method, the Application_Start event handler, etc...). If you must call RegisterClassMap from a code path that executes more than once, you can use IsClassMapRegistered to check whether a class map has already been registered for a class:

```csharp
if (!BsonClassMap.IsClassMapRegistered(typeof(MyClass))) {
    // register class map for MyClass
}
```

**Conventions**

When automapping a class there are a lot of decisions that need to be made. For example:

- Which fields or properties of the class should be serialized
- Which field or property of the class is the "Id"
- What element name should be used in the BSON document
- If the class is being used polymorphically what discriminator values are used
- What should happen if a BSON document has elements we don't recognize
- Does the field or property have a default value
- Should the default value be serialized or ignored
- Should null values be serialized or ignored

Answers to these questions are represented by a set of "conventions". For each convention there is a default convention that is the most likely one you will be using, but you can override individual conventions (and even write your own) as necessary.

If you want to use your own conventions that differ from the defaults simply create an instance of ConventionProfile and set the values you want to override and then register that profile (in other words, tell the default serializer when your special conventions should be used). For example:

```csharp
var myConventions = new ConventionProfile();
// override any conventions you want to be different
BsonClassMap.RegisterConventions(
    myConventions,
    t => t.FullName.StartsWith("MyNamespace.")
);
```

The second parameter is a filter function that defines when this convention profile should be used. In this case we are saying that any classes whose full names begin with "MyNamespace." should use myConventions.

ConventionProfile provides the following methods to allow you to set individual conventions:

- SetDefaultValueConvention
- SetElementNameConvention
- SetExtraElementsMemberConvention
- SetIdGeneratorConvention
- SetIdMemberConvention
- SetIgnoreExtraElementsConvention
- SetIgnoreIfDefaultConvention
- SetIgnoreIfNullConvention
- SetMemberFinderConvention
- SetSerializationOptionsConvention

**Field or property level serialization options**

There are many ways you can control serialization. The previous section discussed conventions, which are a convenient way to control serialization decisions for many classes at once. You can also control serialization at the individual class or field or property level.

Serialization can also be controlled either by decorating your classes and fields or properties with serialization related attributes or by writing code to initialize class maps appropriately. For each aspect of serialization you can control we will be showing both ways.

**Opt-In**

A majority of classes will have their properties mapped automatically. There are some circumstances where this does not happen. For instance, if
your property is read-only, it will not get included in the automapping of a class by default. In order to include the member, you can use the BsonElementAttribute.

```csharp
public class MyClass {
    private readonly string _someProperty;

    [BsonElement]
    public string SomeProperty
    {
        get { return _someProperty; }
    }
}
```

The same result can be achieved without using attributes with the following initialization code:

```csharp
BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.MapProperty(c => c.SomeProperty);
});
```

**Element name**

To specify an element name using attributes, write:

```csharp
public class MyClass {
    [BsonElement("sp")]
    public string SomeProperty { get; set; }
}
```

The same result can be achieved without using attributes with the following initialization code:

```csharp
BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.AutoMap();
    cm.GetMemberMap(c => c.SomeProperty).SetElementName("sp");
});
```

Note that we are first automapping the class and then overriding one particular piece of the class map. If you didn’t call AutoMap first then GetMemberMap would throw an exception because there would be no member maps.

**Element order**

If you want precise control over the order of the elements in the BSON document you can use the Order named parameter to the BsonElement attribute:

```csharp
public class MyClass {
    [BsonElement("sp", Order = 1)]
    public string SomeProperty { get; set; }
}
```

Or using initialization code instead of attributes:

```csharp
BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.AutoMap();
    cm.GetMemberMap(c => c.SomeProperty).SetElementName("sp").SetOrder(1);
});
```

Any fields or properties that do not have an explicit Order will occur after those that do have an Order.

**Identifying the Id field or property**

To identify which field or property of a class is the Id you can write:
public class MyClass {
    [BsonId]
    public string SomeProperty { get; set; }
}

Or using initialization code instead of attributes:

BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.AutoMap();
    cm.SetIdMember(cm.GetMemberMap(c => c.SomeProperty));
});

When not using AutoMap, you can also map a field or property and identify it as the Id in one step as follows:

BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.MapIdProperty(c => c.SomeProperty);
    // mappings for other fields and properties
});

Selecting an IdGenerator to use for an Id field or property

When you Insert a document the C# driver checks to see if the Id member has been assigned a value, and if not, generates a new unique value for it. Since the Id member can be of any type, the driver requires the help of a matching IdGenerator to check whether the Id has a value assigned to it and to generate a new value if necessary. The driver has the following IdGenerators built-in:

- BsonObjectIdGenerator
- CombGuidGenerator
- GuidGenerator
- NullIdChecker
- ObjectIdGenerator
- StringObjectIdGenerator
- ZeroIdChecker<T>

Some of these IdGenerators are used automatically for commonly used Id types:

- BsonObjectIdGenerator is used for BsonObjectId
- GuidGenerator is used for Guid
- ObjectIdGenerator is used for ObjectId
- StringObjectIdGenerator is used for strings represented externally as ObjectId

To select an IdGenerator to use for your Id field or property write:

public class MyClass {
    [BsonId(IdGenerator = typeof(CombGuidGenerator))]
    public Guid Id { get; set; }
}

Or using initialization code instead of attributes:

BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.AutoMap();
    cm.IdMemberMap.SetIdGenerator(CombGuidGenerator.Instance);
});

You could also say that you want to use the CombGuidGenerator for all Guids. In this case you would write:

BsonSerializer.RegisterIdGenerator(
    typeof(Guid),
    CombGuidGenerator.Instance
);

The NullIdChecker and ZeroIdChecker<T> IdGenerators can be used when you don’t have an IdGenerator for an Id type but you want to enforce
that the Id is not null or zero. These pseudo-IdGenerators throw an exception if their GenerateId method is called. You can select it for an individual member just like a CombGuidGenerator was selected in the previous example, or you can turn on one or both of these IdGenerators for all types as follows:

```csharp
BsonSerializer.UseNullIdChecker = true; // used for reference types
BsonSerializer.UseZeroIdChecker = true; // used for value types
```

Note: in version 1.0 of the C# Driver NullableChecker and ZeroIdChecker<T> were always used, but it was decided that their use should be optional, since null and zero are valid values for an Id as far as the server is concerned, so they should only be considered an error if the developer has specifically said they should be.

**Ignoring a field or property**

When constructing a class map manually you can ignore a field or property simply by not adding it to the class map. When using AutoMap you need a way to specify that a field or property should be ignored. To do so using attributes write:

```csharp
public class MyClass {
    [BsonIgnore]
    public string SomeProperty { get; set; }
}
```

Or using initialization code instead of attributes:

```csharp
BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.AutoMap();
    cm.UnmapProperty(c => c.SomeProperty);
});
```

In this case AutoMap will have initially added the property to the class map automatically but then UnmapProperty will remove it.

**Ignoring null values**

By default null values are serialized to the BSON document as a BSON Null. An alternative is to serialize nothing to the BSON document when the field or property has a null value. To specify this using attributes write:

```csharp
public class MyClass {
    [BsonIgnoreIfNull]
    public string SomeProperty { get; set; }
}
```

Or using initialization code instead of attributes:

```csharp
BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.AutoMap();
    cm.GetMemberMap(c => c.SomeProperty).SetIgnoreIfNull(true);
});
```

**Default values**

You can specify a default value for a field or property as follows:

```csharp
public class MyClass {
    [BsonDefaultValue("abc")]
    public string SomeProperty { get; set; }
}
```

Or using initialization code instead of attributes:
BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.AutoMap();
    cm.GetMemberMap(c => c.SomeProperty).SetDefaultValue("abc");
});

You can also control whether default values are serialized or not (the default is yes). To not serialize default values using attributes write:

```csharp
public class MyClass {
    [BsonDefaultValue("abc")]
    [BsonIgnoreIfDefault]
    public string SomeProperty { get; set; }
}
```

Or using initialization code instead of attributes:

```csharp
BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.AutoMap();
    cm.GetMemberMap(c => c.SomeProperty)
        .SetDefaultValue("abc")
        .SetIgnoreIfDefault(true);
});
```

**Ignoring a member based on a ShouldSerializeXyz method**

Sometimes the decision whether to serialize a member or not is more complicated than just whether the value is null or equal to the default value. You can write a method that determines whether a value should be serialized. Usually the method for member Xyz is named ShouldSerializeXyz. If you follow this naming convention then AutoMap will automatically detect the method and use it. For example:

```csharp
public class Employee {
    ObjectId Id { get; set; }
    [BsonDateTimeOptions(DateOnly = true)]
    public DateTime DateOfBirth { get; set; }

    public bool ShouldSerializeDateOfBirth() {
        return DateOfBirth > new DateTime(1900, 1, 1);
    }
}
```

Or using initialization code instead of naming conventions:

```csharp
BsonClassMap.RegisterClassMap<Employee>(cm => {
    cm.AutoMap();
    cm.GetMemberMap(c => c.DateOfBirth).SetShouldSerializeMethod(
        obj => ((Employee)obj).DateOfBirth > new DateTime(1900, 1, 1));
});
```

**Identifying required fields**

Normally, the deserializer doesn't care if the document being deserialized doesn't have a matching element for every field or property of the class. The members that don't have a matching element simply get assigned their default value (or null if they don't have a default value).

If you want to make an element in the document be required, you can mark an individual field or property like this:

```csharp
public class MyClass {
    public ObjectId Id { get; set; }
    [BsonRequired]
    public string X { get; set; }
}
```
Specifying the serializer

There are times when a specific serializer needs to be used rather than letting the Bson library choose. This can be done in a couple of ways:

```csharp
public class MyClass {
    public ObjectId Id { get; set; }
    [BsonSerializer(typeof(MyCustomStringSerializer))]
    public string X { get; set; }
}
```

Or using initialization code instead attributes:

```csharp
BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.AutoMap();
    cm.GetMemberMap(c => c.X).SetIsRequired(true);
});
```

Serialization Options

Serialization of some classes can be more finely controlled using serialization options (which are represented using classes that implement the IBsonSerializationOptions interface). Whether a class uses serialization options or not, and which ones, depends on the particular class involved. The following sections describe the available serialization option classes and the classes that use them.

DateTimeSerializationOptions

These serialization options control how a DateTime is serialized. For example:

```csharp
public class MyClass {
    [BsonDateTimeOptions(DateOnly = true)]
    public DateTime DateOfBirth { get; set; }
    [BsonDateTimeOptions(Kind = DateTimeKind.Local)]
    public DateTime AppointmentTime { get; set; }
}
```

Here we are specifying that the DateOfBirth value holds a date only (so the TimeOfDay component must be zero). Additionally, because this is a date only, no timezone conversions at all will be performed. The AppointmentTime value is in local time and will be converted to UTC when it is serialized and converted back to local time when it is deserialized.

You can specify the same options using initialization code instead of attributes:

```csharp
BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.AutoMap();
    cm.GetMemberMap(c => c.DateOfBirth)
        .SetSerializationOptions(new DateTimeSerializationOptions { DateOnly = true });
    cm.GetMemberMap(c => c.AppointmentTime)
        .SetSerializationOptions(new DateTimeSerializationOptions { Kind = DateTimeKind.Local });
});
```

DateTimeSerializationOptions are supported by the serializers for the following classes: BsonDateTime and DateTime.

DictionarySerializationOptions

When serializing dictionaries there are several alternative ways that the contents of the dictionary can be represented. The different ways are
public enum DictionaryRepresentation {
    Dynamic,
    Document,
    ArrayOfArrays,
    ArrayOfDocuments
}

A dictionary represented as a Document will be stored as a BsonDocument, and each entry in the dictionary will be represented by a BsonElement with the name equal to the key of the dictionary entry and the value equal to the value of the dictionary entry. This representation can only be used when all the keys in a dictionary are strings that are valid element names.

A dictionary represented as an ArrayOfArrays will be stored as a BsonArray of key/value pairs, where each key/value pair is stored as a nested two-element BsonArray where the two elements are the key and the value of the dictionary entry. This representation can be used even when the keys of the dictionary are not strings. This representation is very general and compact, and is the default representation when Document does not apply. One problem with this representation is that it is difficult to write queries against it, which motivated the introduction in the 1.2 version of the driver of the ArrayOfDocuments representation.

A dictionary represented as an ArrayOfDocuments will be stored as a BsonArray of key/value pairs, where each key/value pair is stored as a nested two-element BsonDocument of the form { k : key, v : value }. This representation is just as general as the ArrayOfArrays representation, but because the keys and values are tagged with element names it is much easier to write queries against it. For backward compatibility reasons this is not the default representation.

If the Dynamic representation is specified, the dictionary key values are inspected before serialization, and if all the keys are strings which are also valid element names, then the Document representation will be used, otherwise the ArrayOfArrays representation will be used.

If no other representation for a dictionary is specified, then Dynamic is assumed.

You can specify a DictionarySerializationOption as follows:

```csharp
public class C {
    public ObjectId Id;
    [BsonDictionaryOptions(DictionaryRepresentation.ArrayOfDocuments)]
    public Dictionary<string, int> Values;
}
```

Or using initialization code instead of attributes:

```csharp
BsonClassMap.RegisterClassMap<C>(cm => {
    cm.AutoMap();
    cm.GetMemberMap(c => c.Values)
        .SetSerializationOptions(DictionarySerializationOptions.ArrayOfDocuments);
});
```

DictionarySerializationOptions are supported by the serializers for the following classes: the generic classes and interfaces Dictionary, IDictionary, SortedDictionary and SortedList, and the non-generic classes and interfaces Hashtable, IDictionary, ListDictionary, OrderedDictionary and SortedList.

### RepresentationSerializationOptions

For some .NET primitive types you can control what BSON type you want used to represent the value in the BSON document. For example, you can specify whether a char value should be represented as a BSON Int32 or as a one-character BSON String:

```csharp
public class MyClass {
    [BsonRepresentation(BsonType.Int32)]
    public char RepresentAsInt32 { get; set; }
    [BsonRepresentation(BsonType.String)]
    public char RepresentAsString { get; set; }
}
```

Or using initialization code instead of attributes:
One case that deserves special mention is representing a string externally as an ObjectId. For example:

```csharp
public class Employee {
    [BsonRepresentation(BsonType.ObjectId)]
    public string Id { get; set; }
    // other properties
}
```

In this case the serializer will convert the ObjectId to a string when reading data from the database and will convert the string back to an ObjectId when writing data to the database (the string value must be a valid ObjectId). Typically this is done when you want to keep your domain classes free of any dependencies on the C# driver, so you don't want to declare the Id as an ObjectId. String serves as a neutral representation that is at the same time easily readable for debugging purposes. To keep your domain classes free of dependencies on the C# driver you also won't want to use attributes, so you can accomplish the same thing using initialization code instead of attributes:

```csharp
BsonClassMap.RegisterClassMap<Employee>(cm => {
    cm.AutoMap();
    cm.IdMemberMap.SetRepresentation(BsonType.ObjectId);
});
```

Class level serialization options

There are several serialization options that are related to the class itself instead of to any particular field or property. You can set these class level options either by decorating the class with serialization related attributes or by writing initialization code. As usual, we will show both ways in the examples.

**Ignoring extra elements**

When a BSON document is deserialized the name of each element is used to look up a matching field or property in the class map. Normally, if no matching field or property is found, an exception will be thrown. If you want to ignore extra elements during deserialization, use the following attribute:

```csharp
[IgnoreExtraElements]
public MyClass {
    // fields and properties
}
```

Or using initialization code instead of attributes:

```csharp
BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.AutoMap();
    cm.SetIgnoreExtraElements(true);
});
```

**Supporting extra elements**

You can design your class to be capable of handling any extra elements that might be found in a BSON document during deserialization. To do so, you must have a property of type BsonDocument and you must identify that property as the one that should hold any extra elements that are found (or you can name the property "ExtraElements" so that the default ExtraElementsMemberConvention will find it automatically). For example:
public MyClass {
    // fields and properties
    [BsonExtraElements]
    public BsonDocument CatchAll { get; set; }
}

Or using initialization code instead of attributes:

BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.AutoMap();
    cm.SetExtraElementsMember(cm.GetMemberMap(c => c.CatchAll));
});

When a BSON document is deserialized any extra elements found will be stored in the extra elements BsonDocument property. When the class is serialized the extra elements will be serialized also. One thing to note though is that the serialized class will probably not have the elements in exactly the same order as the original document. All extra elements will be serialized together when the extra elements member is serialized.

**Polymorphic classes and discriminators**

When you have a class hierarchy and will be serializing instances of varying classes to the same collection you need a way to distinguish one from another. The normal way to do so is to write some kind of special value (called a “discriminator”) in the document along with the rest of the elements that you can later look at to tell them apart. Since there are potentially many ways you could discriminate between actual types, the default serializer uses conventions for discriminators. The default serializer provides two standard discriminators: ScalarDiscriminatorConvention and HierarchicalDiscriminatorConvention. The default is the HierarchicalDiscriminatorConvention, but it behaves just like the ScalarDiscriminatorConvention until certain options are set to trigger its hierarchical behavior (more on this later).

The default discriminator conventions both use an element named "_t" to store the discriminator value in the BSON document. This element will normally be the second element in the BSON document (right after the "_id"). In the case of the ScalarDiscriminatorConvention the value of "_t" will be a single string. In the case of the HierarchicalDiscriminatorConvention the value of "_t" will be an array of discriminator values, one for each level of the class inheritance tree (again, more on this later).

While you will normally be just fine with the default discriminator convention, you might have to write a custom discriminator convention if you must inter-operate with data written by another driver or object mapper that uses a different convention for its discriminators.

**Setting the discriminator value**

The default value for the discriminator is the name of the class (without the namespace part). You can specify a different value using attributes:

[BsonDiscriminator("myclass")]
public MyClass {
    // fields and properties
}

Or using initialization code instead of attributes:

BsonClassMap.RegisterClassMap<MyClass>(cm => {
    cm.AutoMap();
    cm.SetDiscriminator("myclass");
});

**Specifying known types**

When deserializing polymorphic classes it is important that the serializer know about all the classes in the hierarchy before deserialization begins. If you ever see an error message about an “Unknown discriminator” it is because the deserializer can’t figure out the class for that discriminator. If you are mapping your classes programatically simply make sure that all classes in the hierarchy have been mapped before beginning deserialization. When using attributes and automapping you will need to inform the serializer about known types (i.e. subclasses) it should create class maps for. Here is an example of how to do this:
The `BsonKnownTypes` attribute lets the serializer know what subclasses it might encounter during deserialization, so when `Animal` is automapped the serializer will also automap `Cat` and `Dog` (and recursively, `Lion` and `Tiger` as well).

Or using initialization code instead of attributes:

```csharp
BsonClassMap.RegisterClassMap<Animal>();
BsonClassMap.RegisterClassMap<Cat>();
BsonClassMap.RegisterClassMap<Dog>();
BsonClassMap.RegisterClassMap<Lion>();
BsonClassMap.RegisterClassMap<Tiger>();
```

### Scalar and hierarchical discriminators

Normally a discriminator is simply the name of the class (although it could be different if you are using a custom discriminator convention or have explicitly specified a discriminator for a class). So a collection containing a mix of different type of `Animal` documents might look like:

```csharp
{ _t : "Animal", ... }
{ _t : "Cat", ... }
{ _t : "Dog", ... }
{ _t : "Lion", ... }
{ _t : "Tiger", ... }
```

Sometimes it can be helpful to record a hierarchy of discriminator values, one for each level of the hierarchy. To do this, you must first mark a base class as being the root of a hierarchy, and then the default `HierarchicalDiscriminatorConvention` will automatically record discriminators as array values instead.

To identify `Animal` as the root of a hierarchy use the `BsonDiscriminator` attribute with the `RootClass` named parameter:

```csharp
[BsonDiscriminator(RootClass = true)]
[BsonKnownTypes(typeof(Cat), typeof(Dog))]
public class Animal {
}
```

// the rest of the hierarchy as before

Or using initialization code instead of attributes:

```csharp
BsonClassMap.RegisterClassMap<Animal>(cm => {
    cm.AutoMap();
    cm.SetIsRootClass(true);
});
BsonClassMap.RegisterClassMap<Cat>();
BsonClassMap.RegisterClassMap<Dog>();
BsonClassMap.RegisterClassMap<Lion>();
BsonClassMap.RegisterClassMap<Tiger>();
```
Now that you have identified Animal as a root class, the discriminator values will look a little bit different:

```plaintext
{ _t : "Animal", ... }
{ _t : ["Animal", "Cat"], ... }
{ _t : ["Animal", "Dog"], ... }
{ _t : ["Animal", "Cat", "Lion"], ... }
{ _t : ["Animal", "Cat", "Tiger"], ... }
```

The main reason you might choose to use hierarchical discriminators is because it makes it possibly to query for all instances of any class in the hierarchy. For example, to read all the Cat documents we can write:

```csharp
var query = Query.EQ("_t", "Cat");
var cursor = collection.FindAs<Animal>(query);
foreach (var cat in cursor) {
    // process cat
}
```

This works because of the way MongoDB handles queries against array values.

**Customizing serialization**

There are several ways you can customize serialization:

1. Implement ISupportInitialize
2. Make a class responsible for its own serialization
3. Supplementing the default serializer
4. Write a custom serializer
5. Write a custom attribute
6. Write a custom Id generator
7. Write a custom convention

**Implementing ISupportInitialize**

The driver respects an entity implementing ISupportInitialize which contains 2 methods, BeginInit and EndInit. These method are called before deserialization begins and after it is complete. It is useful for running operations before or after deserialization such as handling schema changes are pre-calculating some expensive operations.

**Make a class responsible for its own serialization**

One way you can customize how a class is serialized is to make it responsible for its own serialization. You do so by implementing the IBsonSerializable interface:

```csharp
public class MyClass : IBsonSerializable {
    // implement Deserialize method
    // implement Serialize method
}
```

You also must implement the GetDocumentId and SetDocumentId methods. If your class is never used as a root document these methods can just be stubs that throw a NotSupportedException. Otherwise, return true from GetDocumentId if the value passed in has an Id, and set the Id value in SetDocumentId.

There is nothing else you have to do besides implementing this interface. The BSON Library automatically checks whether objects being serialized implement this interface and if so routes serialization calls directly to the classes.

This can be a very efficient way to customize serialization, but it does have the drawback that it pollutes your domain classes with serialization details, so there is also the option of writing a custom serializer as described next.

**Supplementing the default serializer provider**

You can register your own serialization provider to supplement the default serializer. Register it like this:

```csharp
IBsonSerializationProvider myProvider;
BsonSerializer.RegisterSerializationProvider(myProvider);
```
You should register your provider as early as possible. Your provider will be called first before the default serializer. You can delegate handling of any types your custom provider isn’t prepared to handle to the default serializer by returning null from GetSerializer.

**Write a custom serializer**

A custom serializer can handle serialization of your classes without requiring any changes to those classes. This is a big advantage when you either don't want to modify those classes or can't (perhaps because you don't have control over them). You must register your custom serializer so that the BSON Library knows of its existence and can call it when appropriate.

If you write a custom serializer you will have to become familiar with the BsonReader and BsonWriter abstract classes, which are not documented here, but are relatively straightforward to use. Look at the existing serializers in the driver for examples of how BsonReader and BsonWriter are used.

To implement and register a custom serializer you would:

```csharp
// MyClass is the class for which you are writing a custom serializer
public MyClass {
}

// MyClassSerializer is the custom serializer for MyClass
public MyClassSerializer : IBsonSerializer {
    // implement Deserializer
    // implement GetDefaultSerializationOptions
    // implement Serializer
}

// register your custom serializer
BsonSerializer.RegisterSerializer(
    typeof(MyClass),
    new MyClassSerializer()
);
```

You can also decorate the target class with a BsonSerializer attribute instead of using the BsonSerializer.RegisterSerializer method:

```csharp
[BsonSerializer(typeof(MyClassSerializer))]
public MyClass {
}
```

The IBsonSerializer interface is all that is necessary for serialization. However, there are some extension interfaces that will enable further use in other parts of the API such as saving a class or LINQ.

If your class is used as a root document, you will need to implement the IBsonIdProvider interface in order for “Saving” the document to function. MongoCollection.Save requires a document identity in order to know if it should generate an insert or update statement. Below is the extension to the above MyClassSerializer.

```csharp
public MyClassSerializer : IBsonSerializer, IBsonIdProvider {
    // ...
    // implement GetDocumentId
    // implement SetDocumentId
}
```

In order to enable LINQ to properly construct type-safe queries using a custom serializer, it needs access to member information or array information. If your custom serializer is for a class, as MyClassSerializer is above, then you should implement IBsonDocumentSerializer.

```csharp
public MyClassSerializer : IBsonSerializer, IBsonDocumentSerializer {
    // ...
    // implement GetMemberSerializationInfo
}
```

If, however, your class is a collection that should be serialized as an array, it should implement IBsonArraySerializer.
To debug a custom serializer you can either insert a document containing a value serialized by your custom serializer into some collection and then use the mongo shell to examine what the resulting document looks like. Alternatively you can use the ToJson method to see the result of the serializer without having to insert anything into a collection as follows:

```csharp
// assume a custom serializer has been registered for class C
var c = new C();
var json = c.ToJson();
// inspect the json string variable to see how c was serialized
```

**Write a custom attribute**

The auto mapping ability of BSON library utilizes attributes that implement IBsonClassMapModifier or IBsonMemberMapModifier for class level attributes or member level attributes respectively. Each of these interfaces have a single method called Apply that is passed a BsonClassMap or a BsonMemberMap with which it can use any of the public methods and properties to modify the map instance. One example of this would be to create an attribute called BsonEncryptionAttribute that is used to encrypt a string before sending it to the database and decrypt it when reading it back out.

View the existing attributes for examples of how these interfaces function.

**Write a custom Id generator**

You can write your own IdGenerator. For example, suppose you wanted to generate integer Employee Ids:

```csharp
public class EmployeeIdGenerator : IIdGenerator {
    // implement GenerateId
    // implement IsEmpty
}
```

You can specify that this generator be used for Employee Ids using attributes:

```csharp
public class Employee {
    [BsonId(IdGenerator = typeof(EmployeeIdGenerator))]
    public int Id { get; set; }
    // other fields or properties
}
```

Or using initialization code instead of attributes:

```csharp
BsonClassMap.RegisterClassMap<Employee>(cm => {
    cm.AutoMap();
    cm.IdMember.SetIdGenerator(new EmployeeIdGenerator());
});
```

Alternatively, you can get by without an Id generator at all by just assigning a value to the Id property before calling Insert or Save.

**Write a custom convention**

Earlier in this tutorial we discussed replacing one or more of the default conventions. You can either replace them with one of the provided alternatives or you can write your own convention. Writing your own convention varies slightly from convention to convention.

As an example we will write a custom convention to find the Id member of a class (the default convention looks for a member named "Id"). Our custom convention will instead consider any public property whose name ends in "Id" to be the Id for the class. We can implement this convention as follows:
public class EndsWithIdConvention : IIdMemberConvention {
    public string FindIdMember(Type type) {
        foreach (var property in type.GetProperties()) {
            if (property.Name.EndsWith("Id")) {
                return property.Name;
            }
        }
        return null;
    }
}

And we can configure this convention to be used with all of our own classes by writing:

```csharp
var myConventions = new ConventionProfile();
myConventions.SetIdMemberConvention(new EndsWithIdConvention());
BsonClassMap.RegisterConventions(
    myConventions,
    t => t.FullName.StartsWith("MyNamespace."));
```

Warning: because GetProperties is not guaranteed to return properties in any particular order this convention as written will behave unpredictably for a class that contains more than one property whose name ends in "Id".

### Handling Schema Changes

Just because MongoDB is schema-less does not mean that your code can handle a schema-less document. Most likely, if you are using a statically typed language like C# or VB.NET, then your code is not-flexible and needs to be mapped to a known schema.

There are a number of different ways that a schema can change from one version of your application to the next.

1. A new member is added
2. A member is deleted
3. A member is renamed
4. The type of a member is changed
5. The representation of a member is changed

How you handle these is up to you. There primary two different strategies.

1. Write an upgrade script.
2. Incrementally update your documents as they are used

The easiest and most bullet-proof of the strategies is to write an upgrade script. There is effectively no difference to this method between a relational database (SQL Server, Oracle) and MongoDB. Identify the documents that need to be changed and update them.

Alternatively, and not supportable in most relational databases, is the incremental upgrade. The idea is that your documents get updated as they are used. Documents that are never used never get updated. Because of this, there are some definite pitfalls you will need to be aware of.

First, queries against a schema where half the documents are version 1 and half the documents are version 2 could go awry. For instance, if you rename an element, then your query will need to test both the old element name and the new element name to get all the results.

Second, any incremental upgrade code must stay in the code-base until all the documents have been upgraded. For instance, if there have been 3 versions of a document, [1, 2, and 3] and we remove the upgrade code from version 1 to version 2, any documents that still exist as version 1 are un-upgradeable.

So, with that being said, let's talk about handling the schema change variations.

#### A member has been added

When a new member is added to an entity, there is nothing that needs to be done other than restarting the application if you are using the auto mapping features. If not, then you will manually need to map the member in the same way all the other members are getting mapped.

Existing documents will not have this element and it will show up in your class with its default value. You can, of course, specify a default value.

#### A member has been removed

When a member has been removed from an entity, it will continue to exist in the documents. The serializer will throw an exception when this element is seen because it doesn't know what to do with it. The 2 previously discussed items that can be used to combat this are the BsonIgnoreExtraElements class-level attribute and the ExtraElements members.
A member is renamed

When a member has been renamed, it will exist in old documents with the old name and in new documents with the new name. The way to handle incremental upgrades for this rename would be to implement an ExtraElements member in conjunction with ISupportInitialize. For example, let's say that a class used to have a Name property which has now been split into a FirstName and a LastName property.

```csharp
public class MyClass : ISupportInitialize {
    public string FirstName { get; set; }
    public string LastName { get; set; }

    [BsonExtraElements]
    public IDictionary<string, object> ExtraElements { get; set; }

    void ISupportInitialize.BeginInit() {
        // nothing to do at begin
    }

    void ISupportInitialize.EndInit() {
        object nameValue;
        if (!ExtraElements.TryGetValue("Name", out nameValue)) {
            return;
        }

        var name = (string)nameValue;
        // remove the Name element so that it doesn't get persisted back to the database
        ExtraElements.Remove("Name");

        // assuming all names are "First Last"
        var nameParts = name.Split(' ');

        FirstName = nameParts[0];
        LastName = nameParts[1];
    }
}
```

The type of a member is changed

If the .NET type is compatible with the old type (an integer is changed to a double), then everything will continue to work. Otherwise, a custom serializer or a migration script will be required.

The representation of a member is changed

If the representation of a member is changed and the representations are compatible, then everything will continue to work. Otherwise, a custom serializer or a migration script will be required.

CSharp Driver Tutorial

  - ObjectId and BsonObjectId
Introduction

This tutorial introduces the 10gen supported C# Driver for MongoDB. The C# Driver consists of two libraries: the BSON Library and the C# Driver. The BSON Library can be used independently of the C# Driver if desired. The C# Driver requires the BSON Library.

You may also be interested in the C# Driver Serialization Tutorial. It is a separate tutorial because it covers quite a lot of material.

Downloading

The C# Driver is available in source and binary form. While the BSON Library can be used independently of the C# Driver they are both stored in the same repository.

The source may be downloaded from github.com.

We use msysgit as our Windows git client. It can be downloaded from: http://msysgit.github.com/.

To clone the repository run the following commands from a git bash shell:

```bash
$ cd <parentdirectory>
$ git config --global core.autocrlf true
$ git clone git://github.com/mongodb/mongo-csharp-driver.git
$ cd mongo-csharp-driver
$ git config core.autocrlf true
```
You must set the global setting for core.autocrlf to true before cloning the repository. After you clone the repository, we recommend you set the local setting for core.autocrlf to true (as shown above) so that future changes to the global setting for core.autocrlf do not affect this repository. If you then want to change your global setting for core.autocrlf to false run:

```
$ git config --global core.autocrlf false
```

The typical symptom of problems with the setting for core.autocrlf is git reporting that an entire file has been modified (because of differences in the line endings). It is rather tedious to change the setting of core.autocrlf for a repository after it has been created, so it is important to get it right from the start.

You can download a zip file of the source files (without cloning the repository) by clicking on the Downloads button at:

http://github.com/mongodb/mongo-csharp-driver

You can download binaries (in both .msi and .zip formats) from:

http://github.com/mongodb/mongo-csharp-driver/downloads

**Building**

We are currently building the C# Driver with Visual Studio 2010. The name of the solution file is CSharpDriver-2010.sln.

**Dependencies**

The unit tests depend on NUnit 2.5.9, which is included in the dependencies folder of the repository. You can build the C# Driver without installing NUnit, but you must install NUnit before running the unit tests (unless you use a different test runner).

**Running unit tests**

There are three projects containing unit tests:

1. BsonUnitTests
2. DriverUnitTests
3. DriverUnitTestsVB

The BsonUnitTests do not connect to a MongoDB server. The DriverUnitTests and DriverUnitTestsVB connect to an instance of MongoDB running on the default port on localhost.

An easy way to run the unit tests is to set one of the unit test projects as the startup project and configure the project settings as follows (using BsonUnitTests as an example):

- On the Debug tab:
  1. Set Start Action to Start External Program
  2. Set external program to: C:\Program Files (x86)\NUnit 2.5.9\bin\net-2.0\nunit.exe
  3. Set command line arguments to: BsonUnitTests.csproj /config:Debug /run
  4. Set working directory to: the directory where BsonUnitTests.csproj is located

Repeat the above steps for the Release configuration (using /config:Release instead) if you also want to run unit tests for Release builds.

The exact location of the nunit.exe program might vary slightly on your machine.

To run the DriverUnitTests and DriverUnitTestsVB perform the same steps (modified as necessary).

**Installing**

If you want to install the C# Driver on your machine you can use the setup program (see above for download instructions). The setup program is very simple and just copies the DLLs to your specified installation directory.

If you downloaded the binaries zip file simply extract the files and place them wherever you want them to be.

Note: if you download the .zip file Windows might require you to "Unblock" the help file. If Windows asks "Do you want to open this file?" when you double click on the CSharpDriverDocs.chm file, clear the check box next to "Always ask before opening this file" before pressing the Open button. Alternatively, you can right click on the CSharpDriverDocs.chm file and select Properties, and then press the Unblock button at the bottom of the General tab. If the Unblock button is not present then the help file does not need to be unblocked.

**References and namespaces**

To use the C# Driver you must add references to the following DLLs:

1. MongoDB.Bson.dll
2. MongoDB.Driver.dll

As a minimum add the following using statements to your source files:

```c#
using MongoDB.Bson;
using MongoDB.Driver;
```

Additionally you will frequently add some of the following using statements:

```c#
using MongoDB.Driver.Builders;
using MongoDB.Driver.GridFS;
using MongoDB.Driver.Linq;
```

In some cases you might add some of the following using statements if you are using some of the optional parts of the C# Driver:

```c#
using MongoDB.Bson.IO;
using MongoDB.Bson.Serialization;
using MongoDB.Bson.Serialization.Attributes;
using MongoDB.Bson.Serialization.Conventions;
using MongoDB.Bson.Serialization.IdGenerators;
using MongoDB.Bson.Serialization.Options;
using MongoDB.Bson.Serialization.Serializers;
using MongoDB.Driver.Wrappers;
```

The BSON Library

The C# Driver is built on top of the BSON Library, which handles all the details of the BSON specification, including: I/O, serialization, and an in-memory object model of BSON documents.

The important classes of the BSON object model are: BsonType, BsonValue, BsonElement, BsonDocument and BsonArray.

**BsonType**

This enumeration is used to specify the type of a BSON value. It is defined as:

```c#
public enum BsonType {
    Double = 0x01,
    String = 0x02,
    Document = 0x03,
    Array = 0x04,
    Binary = 0x05,
    Undefined = 0x06,
    ObjectId = 0x07,
    Boolean = 0x08,
    DateTime = 0x09,
    Null = 0x0a,
    RegularExpression = 0x0b,
    JavaScript = 0x0d,
    Symbol = 0x0e,
    JavaScriptWithScope = 0x0f,
    Int32 = 0x10,
    Timestamp = 0x11,
    Int64 = 0x12,
    MinKey = 0xff,
    MaxKey = 0x7f
}
```

**BsonValue and subclasses**

BsonValue is an abstract class that represents a typed BSON value. There is a concrete subclass of BsonValue for each of the values defined by the BsonType enum. There are several ways to obtain an instance of BsonValue:

- Use a public constructor (if available) of a subclass of BsonValue
- Use a static Create method of BsonValue
- Use a static Create method of a subclass of BsonValue
- Use a static property of a subclass of BsonValue
- Use an implicit conversion to BsonValue

The advantage of using the static Create methods is that they can return a pre-created instance for frequently used values. They can also return null (which a constructor cannot) which is useful for handling optional elements when creating BsonDocuments using functional construction. The static properties refer to pre-created instances of frequently used values. Implicit conversions allow you to use primitive .NET values wherever a BsonValue is expected, and the .NET value will automatically be converted to a BsonValue.

**BsonType property**

BsonValue has a property called BsonType that you can use to query the actual type of a BsonValue. The following example shows several ways to determine the type of a BsonValue:

```csharp
BsonValue value;
if (value.BsonType == BsonType.Int32) {
    // we know value is an instance of BsonInt32
}
if (value is BsonInt32) {
    // another way to tell that value is a BsonInt32
}
if (value.IsInt32) {
    // the easiest way to tell that value is a BsonInt32
}
```

**As[Type] Properties**

BsonValue has a number of properties that cast a BsonValue to one of its subclasses or a primitive .NET type. It is important to note that these all are casts, not conversions. They will throw an InvalidCastException if the BsonValue is not of the corresponding type. See also the To[Type] methods which do conversions, and the Is[Type] properties which you can use to query the type of a BsonValue before attempting to use one of the As[Type] properties.

```csharp
BsonDocument document;
string name = document["name"].AsString;
int age = document["age"].AsInt32;
BsonDocument address = document["address"].AsBsonDocument;
string zip = address["zip"].AsString;
```

**Is[Type] Properties**

BsonValue has the following boolean properties you can use to test what kind of BsonValue it is. These can be used as follows:

```csharp
BsonDocument document;
int age = -1;
if (document.Contains["age"] && document["age"].IsInt32) {
    age = document["age"].AsInt32;
}
```

**To[Type] conversion methods**

Unlike the As[Type] methods, the To[Type] methods perform some limited conversion between convertible types, like int and double.

The ToBoolean method never fails. It uses JavaScript's definition of truthiness: false, 0, 0.0, NaN, BsonNull, BsonUndefined and "" are false, and everything else is true (include the string "false").

The ToBoolean method is particularly useful when the documents you are processing might have inconsistent ways of recording true/false values:

```csharp
if (employee["ismanager"].ToBoolean()) {
    // we know the employee is a manager
    // works with many ways of recording boolean values
}
```

The ToDouble, ToInt32, and ToInt64 methods never fail when converting between numeric types, though the value might be truncated if it doesn't fit in the target type. A string can be converted to a numeric type, but an exception will be thrown if the string cannot be parsed as a value.
of the target type.

**Static Create methods**

Because `BsonValue` is an abstract class you cannot create instances of `BsonValue` (only instances of concrete subclasses). `BsonValue` has a static `Create` method that takes an argument of type `object` and determines at runtime the actual type of `BsonValue` to create. Subclasses of `BsonValue` also have static `Create` methods tailored to their own needs.

**Implicit conversions**

Implicit conversions are defined from the following .NET types to `BsonValue`:

- `bool`
- `byte[]`
- `DateTime`
- `double`
- `Enum`
- `Guid`
- `int`
- `long`
- `ObjectId`
- `Regex`
- `string`

These eliminate the need for almost all calls to `BsonValue` constructors or `Create` methods. For example:

```csharp
BsonValue b = true; // b is an instance of BsonBoolean
BsonValue d = 3.14159; // d is an instance of BsonDouble
BsonValue i = 1; // i is an instance of BsonInt32
BsonValue s = "Hello"; // s is an instance of BsonString
```

**BsonMaxKey, BsonMinKey, BsonNull and BsonUndefined**

These classes are singletons, so only a single instance of each class exists. You refer to these instances using the static `Value` property of each class:

```csharp
document["status"] = BsonNull.Value;
document["priority"] = BsonMaxKey.Value;
```

Note that C# null and `BsonNull.Value` are two different things. The latter is an actual C# object that represents a BSON null value (it's a subtle difference, but plays an important role in functional construction).

**ObjectId and BsonObjectId**

`ObjectId` is a struct that holds the raw value of a BSON `ObjectId`. `BsonObjectId` is a subclass of `BsonValue` whose `Value` property is of type `ObjectId`.

Here are some common ways of creating `ObjectId` values:

```csharp
var id1 = new ObjectId(); // same as ObjectId.Empty
var id2 = ObjectId.Empty; // all zeroes
var id3 = ObjectId.GenerateNewId(); // generates new unique Id
var id4 = ObjectId.Parse("4dad90129c294e7a5b6aa8"); // parses a 24 hex digit string
```

Note that the first example behaves differently in C# than in JavaScript. In C# it creates an `ObjectId` of all zeroes, but in JavaScript it generates a new unique Id. This difference can't be avoided because in C# the default constructor of a value type always initializes the value to all zeros.

**BsonElement**

A `BsonElement` is a name/value pair, where the value is a `BsonValue`. It is used as the building block of `BsonDocument`, which consists of zero or more elements. You will rarely create `BsonElements` directly, as they are usually created indirectly as needed. For example:

```csharp
document.Add(new BsonElement("age", 21)); // OK, but next line is shorter
document.Add("age", 21); // creates BsonElement automatically
```
**BsonDocument**

A BsonDocument is a collection of name/value pairs (represented by BsonElements). It is an in-memory object model of a BSON document. There are three ways to create and populate a BsonDocument:

1. Create a new document and call Add and Set methods
2. Create a new document and use the fluent interface Add and Set methods
3. Create a new document and use C#'s collection initializer syntax (recommended)

**BsonDocument constructor**

BsonDocument has the following constructors:

- BsonDocument()
- BsonDocument(string name, BsonValue value)
- BsonDocument(BsonElement element)
- BsonDocument(Dictionary<string, object> dictionary)
- BsonDocument(Dictionary<string, object> dictionary, IEnumerable<string> keys)
- BsonDocument(IDictionary dictionary)
- BsonDocument(IDictionary dictionary, IEnumerable<string> keys)
- BsonDocument(IDictionary<string, object> dictionary)
- BsonDocument(IDictionary<string, object> dictionary, IEnumerable<string> keys)
- BsonDocument(IDictionary<string, object> dictionary)
- BsonDocument(IDictionary<string, object> dictionary, IEnumerable<string> keys)
- BsonDocument(IDictionary<string, object> dictionary)
- BsonDocument(IDictionary<string, object> dictionary, IEnumerable<string> keys)
- BsonDocument(BsonDocument, params BsonElement[] elements)
- BsonDocument(bool allowDuplicateNames)

The first two are the ones you are most likely to use. The first creates an empty document, and the second creates a document with one element (in both cases you can of course add more elements).

All the constructors (except the one with allowDuplicateNames) simply call the Add method that takes the same parameters, so refer to the corresponding Add method for details about how the new document is initially populated.

A BsonDocument normally does not allow duplicate names, but if you must allow duplicate names call the constructor with the allowDuplicateNames parameter and pass in true. It is not recommended that you allow duplicate names, and this option exists only to allow handling existing BSON documents that might have duplicate names. MongoDB makes no particular guarantees about whether it supports documents with duplicate names, so be cautious about sending any such documents you construct to the server.

**Create a new document and call Add and Set methods**

This is a traditional step by step method to create and populate a document using multiple C# statements. For example:

```csharp
BsonDocument book = new BsonDocument();
book.Add("author", "Ernest Hemingway");
book.Add("title", "For Whom the Bell Tolls");
```

**Create a new document and use the fluent interface Add and Set methods**

This is similar to the previous approach but the fluent interface allows you to chain the various calls to Add so that they are all a single C# statement. For example:

```csharp
BsonDocument book = new BsonDocument()
    .Add("author", "Ernest Hemingway")
    .Add("title", "For Whom the Bell Tolls");
```

**Create a new document and use C#'s collection initializer syntax (recommended)**

This is the recommended way to create and initialize a BsonDocument in one statement. It uses C#'s collection initializer syntax:

```csharp
BsonDocument book = new BsonDocument {
    [ "author", "Ernest Hemingway" ],
    [ "title", "For Whom the Bell Tolls" ]
};
```

The compiler translates this into calls to the matching Add method:
BsonDocument book = new BsonDocument();
    book.Add("author", "Ernest Hemingway");
    book.Add("title", "For Whom the Bell Tolls");

A common mistake is to forget the inner set of braces. This will result in a compilation error. For example:

BsonDocument bad = new BsonDocument {
    "author", "Ernest Hemingway"
};

is translated by the compiler to:

BsonDocument bad = new BsonDocument();
bad.Add("author");
bad.Add("Ernest Hemingway");

which results in a compilation error because there is no Add method that takes a single string argument.

Creating nested BSON documents

Nested BSON documents are created by setting the value of an element to a BSON document. For example:

BsonDocument nested = new BsonDocument {
    { "name", "John Doe" },
    { "address", new BsonDocument {
        { "street", "123 Main St." },
        { "city", "Centerville" },
        { "state", "PA" },
        { "zip", 12345}
    } }
};

This creates a top level document with two elements ("name" and "address"). The value of "address" is a nested BSON document.

Add methods

BsonDocument has the following overloaded Add methods:

- Add(BsonElement element)
- Add(Dictionary<string, object> dictionary)
- Add(Dictionary<string, object> dictionary, IEnumerable<string> keys)
- Add(IDictionary dictionary)
- Add(IDictionary dictionary, IEnumerable<string> keys)
- Add(IDictionary<string, object> dictionary)
- Add(IDictionary<string, object> dictionary, IEnumerable<string> keys)
- Add(IDictionary<BsonElement> elements)
- Add(IDictionary<string, BsonValue> elements)
- Add(IDictionary<string, BsonValue value>, bool condition)

It is important to note that sometimes the Add methods don't add a new element. If the value supplied is null (or the condition supplied in the last overload is false) then the element isn't added. This makes it really easy to handle optional elements without having to write any if statements or conditional expressions.

For example:

BsonDocument document = new BsonDocument {
    { "name", name },
    { "city", city }, // not added if city is null
    { "dob", dob, dobAvailable } // not added if dobAvailable is false
};

is more compact and readable than:
BsonDocument document = new BsonDocument();
document.Add("name", name);
if (city != null) {
    document.Add("city", city);
} 
if (dobAvailable) {
    document.Add("dob", dob);
}

If you want to add a BsonNull if a value is missing you have to say so. A convenient way is to use C#'s null coalescing operator as follows:

```
BsonDocument = new BsonDocument {
    { "city", city ?? BsonConstants.Null }
};
```

The IDictionary overloads initialize a BsonDocument from a dictionary. Each key in the dictionary becomes the name of a new element, and each value is mapped to a matching BsonValue and becomes the value of the new element. The overload with the keys parameter lets you select which dictionary entries to load (you might also use the keys parameter to control the order in which the elements are loaded from the dictionary).

Accessing BsonDocument elements

The recommended way to access BsonDocument elements is to use one of the following indexers:

- BsonValue this[int index]
- BsonValue this[string name]
- BsonValue this[string name, BsonValue defaultValue]

Note that the return value of the indexers is BsonValue, not BsonElement. This actually makes BsonDocuments much easier to work with (if you ever need to get the actual BsonElements use GetElement).

We've already seen samples of accessing BsonDocument elements. Here are some more:

```
BsonDocument book;
string author = book["author"].AsString;
DateTime publicationDate = book["publicationDate"].AsDateTime;
int pages = book["pages", -1].AsInt32; // default value is -1
```

**BsonArray**

This class is used to represent BSON arrays. While arrays happen to be represented externally as BSON documents (with a special naming convention for the elements), the BsonArray class is unrelated to the BsonDocument class because they are used very differently.

**Constructors**

BsonArray has the following constructors:

- BsonArray()
- BsonArray(IEnumerable<bool> values)
- BsonArray(IEnumerable<BsonValue> values)
- BsonArray(IEnumerable<DateTime> values)
- BsonArray(IEnumerable<double> values)
- BsonArray(IEnumerable<int> values)
- BsonArray(IEnumerable<long> values)
- BsonArray(IEnumerable<ObjectId> values)
- BsonArray(IEnumerable<string> values)
- BsonArray(IEnumerable values)

All the constructors with a parameter call the matching Add method. The multiple overloads are needed because C# does not provide automatic conversions from IEnumerable<T> to IEnumerable<object>.

**Add and AddRange methods**

Bson Array has the following Add methods:

- BsonArray Add(BsonValue value)
- BsonArray AddRange(IEnumerable<bool> values)
BsonArray AddRange(IEnumerable<BsonValue> values)
BsonArray AddRange(IEnumerable<DateTime> values)
BsonArray AddRange(IEnumerable<double> values)
BsonArray AddRange(IEnumerable<int> values)
BsonArray AddRange(IEnumerable<long> values)
BsonArray AddRange(IEnumerable<ObjectId> values)
BsonArray AddRange(IEnumerable<string> values)
BsonArray AddRange(IEnumerable values)

Note that the Add method takes a single parameter. To create and initialize a BsonArray with multiple values use any of the following approaches:

// traditional approach
BsonArray a1 = new BsonArray();
a1.Add(1);
a2.Add(2);

// fluent interface
BsonArray a2 = new BsonArray().Add(1).Add(2);

// values argument
int[] values = new int[] { 1, 2 };
BsonArray a3 = new BsonArray(values);

// collection initializer syntax
BsonArray a4 = new BsonArray { 1, 2 };

Indexer

Array elements are accessed using an integer index. Like BsonDocument, the type of the elements is BsonValue. For example:

```csharp
BsonArray array = new BsonArray { "Tom", 39 };
string name = array[0].AsString;
int age = array[1].AsInt32;
```

The C# Driver

Up until now we have been focusing on the BSON Library. The remainder of this tutorial focuses on the C# Driver.

Thread safety

Only a few of the C# Driver classes are thread safe. Among them: MongoClient, MongoServer, MongoDBatabase, MongoCollection and MongoGridFS. Common classes you will use a lot that are not thread safe include MongoClient and all the classes from the BSON Library (except BsonSymbolTable which is thread safe). A class is not thread safe unless specifically documented as being thread safe.

All static properties and methods of all classes are thread safe.

MongoClient class

This class serves as the root object for working with a MongoDB server. The connections to the server are handled automatically behind the scenes (a connection pool is used to increase efficiency).

When you are connecting to a replica set you will still use only one instance of MongoClient, which represents the replica set as a whole. The driver automatically finds all the members of the replica set and identifies the current primary.

Instances of this class are thread safe.

By default and unless set otherwise, all operations requiring a WriteConcern use w=1. In other words, by default, all write operations will block until the server has acknowledged the write.

Connection strings

The easiest way to connect to a MongoDB server is to use a connection string. The standard connection string format is:

```
mongodb://[username:password@]hostname[:port][/[database][?options]]
```

The username and password should only be present if you are using authentication on the MongoDB server. These credentials will be the default
credentials for all databases. To authenticate against the admin database append "(admin)" to the username. If you are using different credentials with different databases pass the appropriate credentials to the GetDatabase method.

The port number is optional and defaults to 27017.

To connect to multiple servers, specify the seed list by providing multiple hostnames (and port numbers if required) separated by commas. For example:

```
mongodb://server1,server2:27017,server2:27018
```

This connection string specifies a seed list consisting of three servers (two of which are on the same machine but on different port numbers). Because specifying multiple servers is ambiguous as to whether or not it is a replica set or multiple mongos (in a sharded setup), the driver will go through a discovery phase of connecting to the servers to determine their type. This has a little overhead at connection time and can be avoided by specifying a connection mode in the connection string:

```
mongodb://server1,server2:27017,server2:27018/?connect=replicaset
```

The available connection modes are automatic (the default), direct, replica set, and shardrouter. The rules for connection mode are as follows:

1. If a connect mode is specified other than automatic, it is used.
2. If a replica set name is specified on the connection string (replicaset), then replicaset mode is used.
3. If their is only one server listed on the connection string, then direct mode is used.
4. Otherwise, discovery occurs and the first server to respond determines the connection mode.

If you have multiple servers listed, and one is part of a replica set and another is not, then the connection mode is non-deterministic. Be sure that you are not mixing server types on the connection string.

Should the connection mode resolve to a replica set, the driver will find the primary server even if it is not in the seed list, as long as at least one of the servers in the seed list responds (the response will contain the full replica set and the name of the current primary). In addition, other secondaries will also be discovered and added (or removed) into the mix automatically, even after initial connection. This will enable you to add and remove servers from the replica set and the driver will handle the changes automatically.

As alluded to above, the options part of the connection string is used to set various connection options. Suppose you wanted to connect directly to a member of a replica set regardless of whether it was the current primary or not (perhaps to monitor its status or to issue read only queries against it). You could use:

```
mongodb://server2/?connect=direct;readpreference=nearest
```

The full documentation for connection strings can be found at:

http://www.mongodb.org/display/DOCS/Connections

and read preferences at:

http://docs.mongodb.org/manual/applications/replication/#replica-set-read-preference

**SSL Support**

Support for SSL is baked into the driver. You can configure this via the connection string be adding an "ssl=true" option to the options.

```
mongodb://server2/?ssl=true
```

By default, the server certificate will get validated against the local trusted certificate store. This sometimes causes issues in test environments where test servers don't have signed certs. To alleviate this issue, you can also add an "sslverifycertificate=false" as another connection string option to ignore any certificate errors.

**Authentication**

MongoDB supports a simple and straightforward authentication mechanism. You can read about it on the [security and authentication docs page](http://www.mongodb.org/display/DOCS/Security).

The C# driver supports authentication in a couple of ways. As noted above in connection strings, you can specify default credentials on the connection string. The default credentials are always used as a fallback if no other credentials are supplied.

Supplying credentials can be done in two ways. First, they can be supplied to certain methods at runtime. These credentials will then be used to execute the desired functionality. The other, and more robust way, is to store credentials in a MongoCredentialsStore. MongoCredentials in the
store are keyed by database, so if different databases require different users, then the credentials store is consulted first and, upon a miss, will fall back to the default credentials supplied on the connection string if they exist.

The example below uses the credential store to define admin credentials and credentials for the "foo" database. Access to databases other than "admin" or "foo" will use the connection string supplied default credentials "test".

```csharp
var url = new MongoUrl("mongodb://test:user@localhost:27017");
var settings = MongoClientSettings.FromUrl(url);
var adminCredentials = new MongoCredentials("admin", "user", true);
settings.CredentialsStore.Add("admin", adminCredentials);
var fooCredentials = new MongoCredentials("foo", "user", false);
settings.CredentialsStore.Add("foo", fooCredentials);
var client = new MongoClient(settings);
```

**GetServer method**

You can navigate from an instance of a MongoClient to an instance of MongoServer by using the GetServer method.

**MongoServer class**

The MongoServer class is used to provide more control over the driver. It contains advanced ways of getting a database and pushing a sequence of operations through a single socket in order to guarantee consistency.

**GetDatabase method**

You can navigate from an instance of MongoServer to an instance of MongoDatabase (see next section) using one of the following GetDatabase methods or indexers:

- `MongoDatabase GetDatabase(MongoDatabaseSettings settings)`
- `MongoDatabase GetDatabase(string databaseName)`
- `MongoDatabase GetDatabase(string databaseName, MongoCredentials credentials)`
- `MongoDatabase GetDatabase(string databaseName, MongoCredentials credentials, WriteConcern writeConcern)`
- `MongoDatabase GetDatabase(string databaseName, WriteConcern writeConcern)`

**Sample code:**

```csharp
MongoClient client = new MongoClient(); // connect to localhost
MongoServer server = client.GetServer();
MongoDatabase test = server.GetDatabase("test");
MongoCredentials credentials = new MongoCredentials("username", "password");
MongoDatabase salaries = server.GetDatabase("salaries", credentials);
```

Most of the database settings are inherited from the server object, and the provided overloads of GetDatabase let you override a few of the most commonly used settings. To override other settings, call CreateDatabaseSettings and change any settings you want before calling GetDatabase, like this:

```csharp
var databaseSettings = server.CreateDatabaseSettings("test");
databaseSettings.SlaveOk = true;
var database = server.GetDatabase(databaseSettings);
```

GetDatabase maintains a table of MongoDatabase instances it has returned before, so if you call GetDatabase again with the same parameters you get the same instance back again.

**RequestStart/RequestDone methods**

Sometimes a series of operations needs to be performed on the same connection in order to guarantee correct results. This is rarely the case, and most of the time there is no need to call RequestStart/RequestDone. An example of when this might be necessary is when a series of Inserts are called in rapid succession with a WriteConcern of $w=0, and you want to query that data is in a consistent manner immediately thereafter (with a WriteConcern of $w=0, the writes can queue up at the server and might not be immediately visible to other connections). Using RequestStart you can force a query to be on the same connection as the writes, so the query won't execute until the server has caught up with the writes.

A thread can temporarily reserve a connection from the connection pool by using RequestStart and RequestDone. For example:
using(server.RequestStart(database)) {
    // a series of operations that must be performed on the same connection
}

The database parameter simply indicates some database which you intend to use during this request. This allows the server to pick a connection that is already authenticated for that database (if you are not using authentication then this optimization won’t matter to you). You are free to use any other databases as well during the request.

RequestStart increments a counter (for this thread) which is decremented upon completion. The connection that was reserved is not actually returned to the connection pool until the count reaches zero again. This means that calls to RequestStart can be nested and the right thing will happen.

RequestStart returns an IDisposable. If you do no use RequestStart with a using block, it is imperative that RequestDone be called in order to release the connection.

Other properties and methods

For a reference of other properties and method, see the api documentation.

**MongoDatabase class**

This class represents a database on a MongoDB server. Normally there will be only one instance of this class per database, unless you are using different settings to access the same database, in which case there will be one instance for each set of settings.

Instances of this class are thread safe.

**GetCollection method**

This method returns an object representing a collection in a database. When we request a collection object, we also specify the default document type for the collection. For example:

```csharp
MongoDatabase hr = server.GetDatabase("hr");
MongoCollection<Employee> employees =
    hr.GetCollection<Employee>("employees");
```

A collection is not restricted to containing only one kind of document. The default document type simply makes it more convenient to work with that kind of document, but you can always specify a different kind of document when required.

Most of the collection settings are inherited from the database object, and the provided overloads of GetCollection let you override a few of the most commonly used settings. To override other settings, call CreateCollectionSettings and change any settings you want before calling GetCollection, like this:

```csharp
var collectionSettings = database.CreateCollectionSettings<TDocument>("test");
collectionSettings.SlaveOk = true;
var collection = database.GetCollection(collectionSettings);
```

GetCollection maintains a table of instances it has returned before, so if you call GetCollection again with the same parameters you get the same instance back again.

Other properties and methods

For a reference of other properties and method, see the api documentation.

**MongoCollection<TDefaultDocument> class**

This class represents a collection in a MongoDB database. The <TDefaultDocument> type parameter specifies the type of the default document for this collection.

Instances of this class are thread safe.

**Insert<TDocument> method**

To insert a document in the collection create an object representing the document and call Insert. The object can be an instance of
BsonDocument or of any class that can be successfully serialized as a BSON document. For example:

```csharp
MongoCollection<BsonDocument> books =
    database.GetCollection<BsonDocument>("books");
BsonDocument book = new BsonDocument {
    { "author", "Ernest Hemingway" },
    { "title", "For Whom the Bell Tolls" }
};
books.Insert(book);
```

If you have a class called Book the code might look like:

```csharp
MongoCollection<Book> books = database.GetCollection<Book>("books");
Book book = new Book {
    Author = "Ernest Hemingway",
    Title = "For Whom the Bell Tolls"
};
books.Insert(book);
```

**InsertBatch method**

You can insert more than one document at a time using the InsertBatch method. For example:

```csharp
MongoCollection<BsonDocument> books;
BsonDocument[] batch = {
    new BsonDocument {
        { "author", "Kurt Vonnegut" },
        { "title", "Cat's Cradle" }
    },
    new BsonDocument {
        { "author", "Kurt Vonnegut" },
        { "title", "Slaughterhouse-Five" }
    }
};
books.InsertBatch(batch);
```

When you are inserting multiple documents InsertBatch can be much more efficient than Insert.

**FindOne and FindOneAs methods**

To retrieve documents from a collection use one of the various Find methods. FindOne is the simplest. It returns the first document it finds (when there are many documents in a collection you can’t be sure which one it will be). For example:

```csharp
MongoCollection<Book> books;
Book book = books.FindOne();
```

If you want to read a document that is not of the <TDefaultDocument> type use the FindOneAs method, which allows you to override the type of the returned document. For example:

```csharp
MongoCollection<Book> books;
BsonDocument document = books.FindOneAs<BsonDocument>();
```

In this case the default document type of the collection is Book, but we are overriding that and specifying that the result be returned as an instance of BsonDocument.

**Find and FindAs methods**

The Find and FindAs methods take a query that tells the server which documents to return. The query parameter is of type IMongoQuery. IMongoQuery is a marker interface that identifies classes that can be used as queries. The most common ways to construct a query are to either use the Query builder class or to create a QueryDocument yourself (a QueryDocument is a subclass of BsonDocument that also implements IMongoQuery and can therefore be used as a query object). Also, by using the QueryWrapper class the query can be of any type that can be successfully serialized to a BSON document, but it is up to you to make sure that the serialized document represents a valid query object.
One way to query is to create a QueryDocument object yourself:

```csharp
MongoCollection<BsonDocument> books;
var query = new QueryDocument("author", "Kurt Vonnegut");
foreach (BsonDocument book in books.Find(query)) {
    // do something with book
}
```

Another way to query is to use the Query Builder (recommended):

```csharp
MongoCollection<BsonDocument> books;
var query = Query.EQ("author", "Kurt Vonnegut");
foreach (BsonDocument book in books.Find(query)) {
    // do something with book
}
```

Yet another way to query is to use an anonymous class as the query, but in this case we must wrap the anonymous object:

```csharp
MongoCollection<BsonDocument> books;
var query = Query.Wrap(new { author = "Kurt Vonnegut" });
foreach (BsonDocument book in books.Find(query)) {
    // do something with book
}
```

If you want to read a document of a type that is not the default document type use the FindAs method instead:

```csharp
MongoCollection<BsonDocument> books;
var query = Query<Book>.EQ(b => b.Author, "Kurt Vonnegut");
foreach (Book book in books.FindAs<Book>(query)) {
    // do something with book
}
```

**Save<TDocument> method**

The Save method is a combination of Insert and Update. If the Id member of the document has a value, then it is assumed to be an existing document and Save calls Update on the document (setting the Upsert flag just in case it actually is a new document after all). Otherwise it is assumed to be a new document and Save calls Insert after first assigning a newly generated unique value to the Id member.

For example, you could correct an error in the title of a book using:

```csharp
MongoCollection<BsonDocument> books;
var query = Query.And(
    Query.EQ("author", "Kurt Vonnegut"),
    Query.EQ("title", "Cats Craddle")
);
BsonDocument book = books.FindOne(query);
if (book != null) {
    book["title"] = "Cat's Cradle";
    books.Save(book);
}
```

The TDocument class must have an Id member to be used with the Save method. If it does not you can call Insert instead of Save to insert the document.

**Update method**

The Update method is used to update existing documents. The code sample shown for the Save method could also have been written as:
using Query and Update builders:

```csharp
MongoCollection<BsonDocument> books;
var query = new QueryDocument {
  { "author", "Kurt Vonnegut" },
  { "title", "Cats Cradle" }
};
var update = new UpdateDocument {
  { "$set", new BsonDocument("title", "Cat's Cradle") }
};
BsonDocument updatedBook = books.Update(query, update);
```

**FindAndModify method**

Use FindAndModify when you want to find a matching document and update it in one atomic operation. FindAndModify always updates a single document, and you can combine a query that matches multiple documents with a sort criteria that will determine exactly which matching document is updated. In addition, FindAndModify will return the matching document (either as it was before the update or after) and if you wish you can specify which fields of the matching document to return.

Using the example documented here:

http://www.mongodb.org/display/DOCS/findAndModify+Command

the call to FindAndModify would be written in C# as:

```csharp
var jobs = database.GetCollection("jobs");
var query = Query.And(
    Query.EQ("inprogress", false),
    Query.EQ("name", "Biz report")
);
var sortBy = SortBy.Descending("priority");
var update = Update.
    Set("inprogress", true).
    Set("started", DateTime.UtcNow);
var result = jobs.FindAndModify(
    query,
    sortBy,
    update,
    true // return new document
);
var chosenJob = result.ModifiedDocument;
```

**MapReduce method**

Map/Reduce is a way of aggregating data from a collection. Every document in a collection (or some subset if an optional query is provided) is sent to the map function, which calls emit to produce intermediate values. The intermediate values are then sent to the reduce function to be aggregated.

This example is taken from page 87 of MongoDB: The Definitive Guide, by Kristina Chodorow and Michael Diroll. It counts how many times each key is found in a collection.
Other properties and methods

For a reference of other properties and method, see the api documentation.

**MongoCursor<TDocument> class**

The Find method (and its variations) don't immediately return the actual results of a query. Instead they return a cursor that can be enumerated to retrieve the results of the query. The query isn't actually sent to the server until we attempt to retrieve the first result (technically, when MoveNext is called for the first time on the enumerator returned by GetEnumerator). This means that we can control the results of the query in interesting ways by modifying the cursor before fetching the results.

Instances of MongoCursor are not thread safe, at least not until they are frozen (see below). Once they are frozen they are thread safe because they are read-only (in particular, GetEnumerator is thread safe so the same cursor could be used by multiple threads).

**Enumerating a cursor**

The most convenient way to consume the results of a query is to use the C# foreach statement. For example:

```csharp
var query = Query.EQ("author", "Ernest Hemingway");
var cursor = books.Find(query);
foreach (var book in cursor) {
    // do something with book
}
```

You can also use any of the extensions methods defined by LINQ for IEnumerable<T> to enumerate a cursor:

```csharp
var query = Query.EQ("author", "Ernest Hemingway");
var cursor = books.Find(query);
var firstBook = cursor.FirstOrDefault();
var lastBook = cursor.LastOrDefault();
```

In the above example, the query is actually sent to the server twice (once when FirstOrDefault is called and again when LastOrDefault is called).

It is important that a cursor cleanly release any resources it holds. The key to guaranteeing this is to make sure the Dispose method of the enumerator is called. The foreach statement and the LINQ extension methods all guarantee that Dispose will be called. Only if you enumerate the cursor manually are you responsible for calling Dispose.

**Modifying a cursor before enumerating it**

A cursor has several properties that can be modified before it is enumerated to control the results returned. There are two ways to modify a cursor:

```csharp
var map =
"function() {
    for (var key in this) {
        emit(key, { count : 1 });
    }
}"

var reduce =
"function(key, emits) {
    total = 0;
    for (var i in emits) {
        total += emits[i].count;
    }
    return { count : total };";

var mr = collection.MapReduce(map, reduce);
foreach (var document in mr.GetResults()) {
    Console.WriteLine(document.ToJson());
}
```
1. modify the properties directly
2. use the fluent interface to set the properties

For example, if we want to skip the first 100 results and limit the results to the next 10, we could write:

```javascript
var query = Query.EQ("status", "pending");
var cursor = tasks.Find(query);
cursor.Skip = 100;
cursor.Limit = 10;
foreach (var task in cursor) {
    // do something with task
}
```

or using the fluent interface:

```javascript
var query = Query.EQ("status", "pending");
foreach (var task in tasks.Find(query).SetSkip(100).SetLimit(10)) {
    // do something with task
}
```

The fluent interface works well when you are setting only a few values. When setting more than a few you might prefer to use the properties approach.

Once you begin enumerating a cursor it becomes “frozen” and you can no longer change any of its properties. So you must set all the properties before you start enumerating it.

**Modifiable properties of a cursor**

The following properties of a cursor are modifiable:

- BatchSize (SetBatchSize)
- Fields (SetFields)
- Flags (SetFlags)
- Limit (SetLimit)
- Options (SetOption and SetOptions)
- SerializationOptions (SetSerializationOptions)
- Skip (SetSkip)
- SlaveOk (SetSlaveOk)

The method names in parenthesis are the corresponding fluent interface methods.

The fluent interface also supports additional options that aren't used very frequently and are not exposed as properties:

- SetHint
- SetMax
- SetMaxScan
- SetMin
- SetShowDiskLoc
- SetSnapshot
- SetSortOrder

**Other methods**

MongoCursor has a few methods used for some special purpose operations:

- Clone
- Count
- Explain
- Size

**WriteConcern class**

There are various levels of WriteConcern, and this class is used to represent those levels. WriteConcern applies only to operations that don't already return a value (so it doesn't apply to queries or commands). It applies to the following MongoCollection methods: Insert, Remove, Save and Update.

The gist of WriteConcern is that after an Insert, Remove, Save or Update message is sent to the server it is followed by a GetLastError command so the driver can verify that the operation succeeded. In addition, when using replica sets it is possible to verify that the information has been replicated to some minimum number of secondary servers.
CSharp getLastError and SafeMode

In the C# driver SafeMode can be set at different levels.

1. At the server level via the connection string:

```csharp
var connectionString = "mongodb://hostname/?safe=true;w=2;wtimeout=30s";
var server = MongoServer.Create(connectionString);
```

2. At the database level:

```csharp
var safemode = SafeMode.W2; // default timeout
// or
var safeMode = SafeMode.Create(2, TimeSpan.FromSeconds(30)); // 30 second timeout
var database = server.GetDatabase("test", safeMode);
```

3. At the collection level:

```csharp
var collection = database.GetCollection("test", safeMode);
```

4. At the operation level:

```csharp
var safeModeResult = collection.Insert(document, safeMode);
```

Each level inherits the setting from the level above it unless overridden.

getLastError is called automatically when any SafeMode other than false is used. An exception is thrown if there was an error, otherwise the SafeModeResult has the information returned by GetLastError.

Driver Syntax Table

The wiki generally gives examples in JavaScript, so this chart can be used to convert those examples to any language.
### Javascript Language Center

MongoDB can be

- Used by clients written in Javascript;
- Uses Javascript internally server-side for certain options such as map/reduce;
- Has a **shell** that is based on Javascript for administrative purposes.

#### node.JS and V8

See the node.JS page.

#### SpiderMonkey

The MongoDB shell extends SpiderMonkey. See the MongoDB shell documentation.

#### Narwhal

- [http://github.com/sergi/narwhal-mongodb](http://github.com/sergi/narwhal-mongodb)

#### MongoDB Server-Side Javascript

Javascript may be executed in the MongoDB server processes for various functions such as query enhancement and map/reduce processing. See [Server-side Code Execution](#).

### Node.js

**Node.js** is used to write event-driven, scalable network programs in server-side JavaScript. It is similar in purpose to Twisted, EventMachine, etc. It runs on Google’s V8.

This is an overview of the available tools and suggested practices for using Node.js with MongoDB. Those wishing to skip to more detailed discussion should check out the [Node.js Driver Manual](#).

**Node.js Driver**

The **MongoDB Node.js driver** is the 10gen-supported driver for MongoDB. In spring 2012 10gen officially adopted the popular Node MongoDB...
Native Project and sponsored the maintainer, Christian Kvalheim, to continue its development. It's written in pure javascript and provides a native asynchronous node.js interface to MongoDB. The driver is optimized for simplicity. It can be used on its own, but it also serves as the basis of several object mapping libraries, such as Mongoose.

- Tutorial
- Node.js Driver README
- Source Code

Installing / Upgrading

The easiest way to install is to use npm:

```
$ npm install mongodb
```

Object Mappers

Because MongoDB is so easy to use, the basic Node.js driver can be the best solution for many applications. However, if you need validations, associations, and other high-level data modeling functions then an Object Document Mapper may be helpful.

Mongoose

Mongoose is the 10gen-supported ODM for Node.js. It has a thriving open source community and includes advanced schema-based features such as async validation, casting, object life-cycle management, pseudo-joins, and rich query builder support.

Install it easily with npm:

```
$ npm install mongoose
```

- Quickstart Tutorial

- Google Group
- Bug reports
- irc: #mongoosejs on freenode

Other notable projects

- Mongoose - The future layer for node-mongodb-native.
- Mongolia - Lightweight MongoDB ORM/Driver Wrapper.
- Mongojo - Somewhat mimics the MongoDB shell api.

Each of these projects build on top of the native Node.js driver and so some knowledge of that is useful, especially if you work with a custom Mongo configuration.

PHP Language Center
Using MongoDB in PHP

To access MongoDB from PHP you will need:

- The MongoDB server running - the server is the "mongod" file, not the "mongo" client (note the "d" at the end)
- The MongoDB PHP driver installed

Installing the PHP Driver

*NIX

Run:

```
sudo pecl install mongo
```

Open your php.ini file and add to it:

```
extension=mongo.so
```

It is recommended to add this to the section with the other "extensions", but it will work from anywhere within the php.ini file.

Restart your web server (Apache, nginx, etc.) for the change to take effect.

See the [installation docs](#) for configuration information and OS-specific installation instructions.

**Note**

pecl requires that pear be installed. For those using apt-get, you may need to run the following:

```
sudo apt-get install php5-dev php5-cli php-pear
```

Windows

- Download the correct driver for your environment from [http://github.com/mongodb/mongo-php-driver/downloads](http://github.com/mongodb/mongo-php-driver/downloads). Thread safe is for running PHP as an Apache module (typical installation), non-thread safe is for CGI.
- Unzip and add the php_mongo.dll file to your PHP extensions directory (usually the "ext" folder in your PHP installation.)
- Add to your php.ini:

```
extension=php_mongo.dll
```

- Restart your web server (Apache, IIS, etc.) for the change to take effect.

For more information, see the Windows section of the [installation docs](#).

Using the PHP Driver

To get started, see the [Tutorial](#). Also check out the [API Documentation](#).

Installing the PHP Driver
The PHP community has created a huge number of libraries to make working with MongoDB easier and integrate it with existing frameworks.

**Libraries and Frameworks**

- **CakePHP**
  - MongoDB datasource for CakePHP. There's also an introductory blog post on using it with Mongo.

- **Codeigniter**
  - MongoDB-Codeigniter-Driver

- **Doctrine**
  - **ODM** (Object Document Mapper) is an experimental Doctrine MongoDB object mapper. The Doctrine\ODM\Mongo namespace is an experimental project for a PHP 5.3 MongoDB Object Mapper. It allows you to easily write PHP 5 classes and map them to collections in MongoDB. You just work with your objects like normal and Doctrine will transparently persist them to Mongo.

  This project implements the same "style" of the Doctrine 2 ORM project interface so it will look very familiar to you and it has lots of the same features and implementations.

- **Drupal**
  - MongoDB Integration - Views (query builder) backend, a watchdog implementation (logging), and field storage.
**Fat-Free Framework**

Fat-Free is a powerful yet lightweight PHP 5.3+ Web development framework designed to help you build dynamic and robust applications - fast!

**Kohana Framework**

- **Mango** at github
  
  An ActiveRecord-like library for PHP, for the Kohana PHP Framework. See also PHP Language Center#MongoDb PHP ODM further down.

**Lithium**

Lithium supports Mongo out-of-the-box.

- **Tutorial** on creating a blog backend.

**Symfony 2**

- **Symfony 2 Logger**
  
  A centralized logger for Symfony applications. See the blog post.

- **sfMongoSessionStorage** - manages session storage via MongoDB with symfony.

- **sfStoragePerformancePlugin** - This plugin contains some extra storage engines (MongoDB and Memcached) that are currently missing from the Symfony (>= 1.2) core.

**TechMVC**

**Thundergrid**

A GridFS Framework for PHP

Thundergrid is a simple framework written in PHP that allows you to rapidly store files in your Mongo database using the GridFS specification.

Using Thundergrid gives you the ability to control exactly how you use GridFS in your scripts, it allows you to list, filter and display objects within GridFS quickly and rapidly.

**Vork**

Vork, the high-performance enterprise framework for PHP natively supports MongoDB as either a primary datasource or used in conjunction with an RDBMS. Designed for scalability & Green-IT, Vork serves more traffic with fewer servers and can be configured to operate without any disk-I/O.

Vork provides a full MVC stack that outputs semantically-correct XHTML 1.1, complies with Section 508 Accessibility guidelines & Zend-Framework coding-standards, has SEO-friendly URLs, employs CSS-reset for cross-browser display consistency and is written in well-documented object-oriented E_STRICT PHP5 code.

An extensive set of tools are built into Vork for ecommerce (cc-processing, SSL, PayPal, AdSense, shipment tracking, QR-codes), Google Maps, translation & internationalization, Wiki, Amazon Web Services, Social-Networking (Twitter, Meetup, ShareThis, YouTube, Flickr) and much more.

**Yii**

- **YiiMongoDbSuite** is an almost complete, ActiveRecord like support for MongoDB in Yii It originally started as a fork of MongoRecord extension written by tyohan, to fix some major bugs, and add full featured suite for MongoDB developers.

**Zend Framework**

- **Shanty Mongo** is a prototype mongodb adapter for the Zend Framework. It's intention is to make working with mongodb documents as natural and as simple as possible. In particular allowing embedded documents to also have custom document classes.

- **ZF Cache Backend**

  A ZF Cache Backend for MongoDB. It support tags and auto-cleaning.

- **There is a Zend_Nosql_Mongo component proposal.**

**Stand-Alone Tools**
Autocomplete for IDEs

PeclMongoPhpDoc gives IDEs information about the Pecl extension to help with autocomplete & docs.

ActiveMongo

ActiveMongo is a really simple ActiveRecord for MongoDB in PHP.
There’s a nice introduction to get you started at http://crodas.org/activemongo.php.

Comfi

Comfi is a Mongo PHP ORM (part of Comfi.com Homebase Framework)

MapReduce API

A MapReduce abstraction layer. See the blog post.

- MongoDB-MapReduce-PHP at github

Mongofilesystem

Filesystem based on MongoDB GridFS. Mongofilesystem will help you use MongoDB GridFS like a typical filesystem, using the familiar PHP commands.

Mandango

Mandango is a simple, powerful and ultrafast Object Document Mapper (ODM) for PHP and MongoDB.

MongoDB Pagination

PHP MongoDB Pagination is the pagination plugin for MongoDB released under MIT License. Simple to install & use. It has been developed under TechMVC 3.0.4, but it's compatible with any 3rd party framework (e.g. Zend (tested)).

MongoDB PHP ODM

MongoDB PHP ODM is a simple object wrapper for the Mongo PHP driver classes which makes using Mongo in your PHP application more like ORM, but without the suck. It is designed for use with Kohana 3 but will also integrate easily with any PHP application with almost no additional effort.

Mongodloid

A nice library on top of the PHP driver that allows you to make more natural queries ($query->query('a == 13 AND b >= 8 && c % 3 == 4'));, abstracts away annoying $-syntax, and provides getters and setters.

- Downloads
- Documentation

MongoQueue

MongoQueue is a PHP queue that allows for moving tasks and jobs into an asynchronous process for completion in the background. The queue is managed by Mongo

MongoQueue is an extraction from online classifieds site Oodle. Oodle uses MongoQueue to background common tasks in order to keep page response times low.

MongoRecord

MongoRecord is a PHP Mongo ORM layer built on top of the PHP Mongo PECL extension

MongoRecord is an extraction from online classifieds site Oodle. Oodle’s requirements for a manageable, easy to understand interface for dealing with the super-scalable Mongo datastore was the primary reason for MongoRecord. It was developed to use with PHP applications looking to add Mongo’s scaling capabilities while dealing with a nice abstraction layer.

Morph

A high level PHP library for MongoDB. Morph comprises a suite of objects and object primitives that are designed to make working with MongoDB in PHP a breeze.

- Morph at github
**simplemongophp**

Very simple layer for using data objects see blog post

- simplemongophp at github

**TURBOPY**

TURBOPY is a cloud based content management framework + IDE using new editing concepts working with mongodb.

**Blogs & HOWTOs**

*How to batch import JSON data output from FFprobe for motion stream analysis*

FFprobe is a stream analyzer that optionally reports in JSON. This example is a PHP script that reads JSON from STDIN, makes an object using json_decode, and inserts the object into a MongoDB database. This script could be used with any program that outputs a JSON stream. A bash script will be used to batch process all files within the current directory. For example, the data may be used for analysis and logging of a day's shoot.

- Batch import Multimedia Stream Data into MongoDB with FFprobe web site
- Code and Sample Output at github

**Ruby Language Center**

This is an overview of the available tools and suggested practices for using Ruby with MongoDB. Those wishing to skip to more detailed discussion should check out the Ruby Driver Tutorial, Getting started with Rails or Rails 3, and MongoDB Data Modeling and Rails. There are also a number of good external resources worth checking out.

- Ruby Driver
  - Installing / Upgrading
  - BSON
- Object Mappers
- Notable Projects
- Presentations

**Ruby Driver**

⚠️ Install the bson_ext gem for any performance-critical applications.

The MongoDB Ruby driver is the 10gen-supported driver for MongoDB. It's written in pure Ruby, with a recommended C extension for speed. The driver is optimized for simplicity. It can be used on its own, but it also serves as the basis of several object mapping libraries, such as MongoMapper.

- Tutorial
- Documentation
- Source Code

**Installing / Upgrading**
The ruby driver is hosted at Rubygems.org. Before installing the driver, make sure you're using the latest version of rubygems:

$ gem update --system

Then install the gems:

$ gem install mongo

To stay on the bleeding edge, you can use the latest source from github:

Using your Gemfile:

```ruby
gem 'mongo', :git => 'git://github.com/mongodb/mongo-ruby-driver.git'
```

Or Manually:

```bash
$ git clone git://github.com/mongodb/mongo-ruby-driver.git
$ cd mongo-ruby-driver/
$ gem build bson.gemspec; gem install bson-x.x.x.gem
$ gem build bson_ext.gemspec; gem install bson_ext-x.x.x.gem
$ gem build mongo.gemspec; gem install mongo-x.x.x.gem
```

**BSON**

In versions of the Ruby driver prior to 0.20, the code for serializing to BSON existed in the mongo gem. Now, all BSON serialization is handled by the required bson gem.

```ruby
gem install bson
```

For significantly improved performance, install the bson_ext gem. Using compiled C instead of Ruby, this gem speeds up BSON serialization greatly.

```bash
gem install bson_ext
```

If you're running on Windows, you'll need the Ruby DevKit installed in order to compile the C extensions.

As long it's in Ruby's load path, bson_ext will be loaded automatically when you require bson.

Note that beginning with version 0.20, the mongo_ext gem is no longer used.

To learn more about the Ruby driver, see the Ruby Tutorial.

**Object Mappers**

Because MongoDB is so easy to use, the basic Ruby driver can be the best solution for many applications.

But if you need validations, associations, and other high-level data modeling functions then an Object Document Mapper may be needed.

In the context of a Rails application these provide functionality equivalent to, but distinct from, ActiveRecord. Because Mongo is a document-based database, these mappers are called Object Document Mappers (ODM) as opposed to Object Relational Mappers (ORM).

Several mappers are available:

- **MongoMapper** from John Nunemaker
- **Mongoid** from Durran Jordan
- **Mongomatic** from Ben Myles
- **MongoODM** from Carlos Paramio
- **MongoModel** from Sam Pohlenz
- **DriverAPILayer** from Alexey Petrushin
All the mappers build on top of the basic Ruby driver and so some knowledge of that is useful, especially if you work with a custom Mongo configuration.

**Notable Projects**

Tools for working with MongoDB in Ruby are being developed daily. A partial list can be found in the Projects and Libraries section of our external resources page.

If you're working on a project that you'd like to have included, let us know.

**Presentations**

*Introduction to MongoDB and Ruby (September 2012)*
*MongoDB & Ruby Presentations*

**Ruby Tutorial**

*Redirection Notice*
This page should redirect to http://api.mongodb.org/ruby/current/file.TUTORIAL.html.

This tutorial gives many common examples of using MongoDB with the Ruby driver. If you’re looking for information on data modeling, see MongoDB Data Modeling and Rails. Links to the various object mappers are listed on our object mappers page.

Interested in GridFS? Checkout GridFS in Ruby.

As always, the latest source for the Ruby driver can be found on github.

**Installation**

The mongo-ruby-driver gem is served through Rubygems.org. To install, make sure you have the latest version of rubygems.

```
gem update --system
```

Next, install the mongo rubygem:

```
gem install mongo
```

The required bson gem will be installed automatically.

For optimum performance, install the bson_ext gem:
After installing, you may want to look at the examples directory included in the source distribution. These examples walk through some of the basics of using the Ruby driver.

The full API documentation can be viewed here.

A Quick Tour

Using the RubyGem

All of the code here assumes that you have already executed the following Ruby code:

```ruby
require 'rubygems'  # not necessary for Ruby 1.9
require 'mongo'
```

Making a Connection

An Mongo::Connection instance represents a connection to MongoDB. You use a Connection instance to obtain an Mongo::DB instance, which represents a named database. The database doesn't have to exist - if it doesn't, MongoDB will create it for you.

You can optionally specify the MongoDB server address and port when connecting. The following example shows three ways to connect to the database "mydb" on the local machine:

```ruby
db = Mongo::Connection.new.db("mydb")
db = Mongo::Connection.new("localhost").db("mydb")
db = Mongo::Connection.new("localhost", 27017).db("mydb")
```

At this point, the `db` object will be a connection to a MongoDB server for the specified database. Each DB instance uses a separate socket connection to the server.

If you're trying to connect to a replica set, see Replica Sets in Ruby.

Listing All Databases

```ruby
connection = Mongo::Connection.new # (optional host/port args)
connection.database_names.each { |name| puts name }
connection.database_info.each { |info| puts info.inspect }
```

Dropping a Database

```ruby
connection.drop_database('database_name')
```

Authentication (Optional)

MongoDB can be run in a secure mode where access to databases is controlled through name and password authentication. When run in this mode, any client application must provide a name and password before doing any operations. In the Ruby driver, you simply do the following with the connected mongo object:

```ruby
auth = db.authenticate(my_user_name, my_password)
```

If the name and password are valid for the database, `auth` will be `true`. Otherwise, it will be `false`. You should look at the MongoDB log for further information if available.

Getting a List Of Collections

Each database has zero or more collections. You can retrieve a list of them from the `db` (and print out any that are there):

```ruby
```
and assuming that there are two collections, name and address, in the database, you would see

```
name
address
```
as the output.

### Getting a Collection

You can get a collection to use using the `collection` method:

```ruby
coll = db.collection("testCollection")
```

This is aliased to the `[]` method:

```ruby
coll = db["testCollection"]
```

Once you have this collection object, you can now do things like insert data, query for data, etc.

### Inserting a Document

Once you have the collection object, you can insert documents into the collection. For example, lets make a little document that in JSON would be represented as

```json
{
  "name": "MongoDB",
  "type": "database",
  "count": 1,
  "info": {
    "x": 203,
    "y": 102
  }
}
```

Notice that the above has an "inner" document embedded within it. To do this, we can use a Hash or the driver's OrderedHash (which preserves key order) to create the document (including the inner document), and then just simply insert it into the collection using the `insert()` method.

```ruby
doc = {"name" => "MongoDB", "type" => "database", "count" => 1, "info" => {
  "x" => 203,
  "y" => 102
}}
coll.insert(doc)
```

### Updating a Document

We can update the previous document using the `update` method. There are a couple ways to update a document. We can rewrite it:

```ruby
doc["name"] = "MongoDB Ruby"
coll.update({"_id" => doc["_id"]}, doc)
```

Or we can use an atomic operator to change a single value:

```ruby
coll.update({"_id" => doc["_id"]}, {"$set" => {"name" => "MongoDB Ruby"}})
```

Read more about updating documents.
Finding the First Document In a Collection using `find_one()`

To show that the document we inserted in the previous step is there, we can do a simple `find_one()` operation to get the first document in the collection. This method returns a single document (rather than the Cursor that the `find()` operation returns).

```ruby
my_doc = coll.find_one()
puts my_doc.inspect
```

and you should see:

```bash
{"_id"=>#<BSON::ObjectID:0x118576c ...>, "name"=>"MongoDB", "info"=>{"x"=>203, "y"=>102}, "type"=>"database", "count"=>1}
```

Note the `_id` element has been added automatically by MongoDB to your document.

Adding Multiple Documents

To demonstrate some more interesting queries, let's add multiple simple documents to the collection. These documents will have the following form:

```ruby
{
  "i" : value
}
```

Here's how to insert them:

```ruby
100.times { |i| coll.insert("i" => i) }
```

Notice that we can insert documents of different "shapes" into the same collection. These records are in the same collection as the complex record we inserted above. This aspect is what we mean when we say that MongoDB is "schema-free".

Counting Documents in a Collection

Now that we've inserted 101 documents (the 100 we did in the loop, plus the first one), we can check to see if we have them all using the `count()` method.

```ruby
puts coll.count()
```

and it should print `101`.

Using a Cursor to get all of the Documents

To get all the documents from the collection, we use the `find()` method. `find()` returns a Cursor object, which allows us to iterate over the set of documents that matches our query. The Ruby driver's Cursor implemented Enumerable, which allows us to use `Enumerable#each`, `Enumerable#map`, etc. For instance:

```ruby
coll.find().each { |row| puts row.inspect }
```

and that should print all 101 documents in the collection.

Getting a Single Document with a Query

We can create a query hash to pass to the `find()` method to get a subset of the documents in our collection. For example, if we wanted to find the document for which the value of the "i" field is 71, we would do the following:

```ruby
coll.find("i" => 71).each { |row| puts row.inspect }
```

and it should just print just one document:
Getting a Set of Documents With a Query

We can use the query to get a set of documents from our collection. For example, if we wanted to get all documents where \(i\) > 50, we could write:

```ruby
coll.find("i" => "$gt" => 50).each { |row| puts row }
```

which should print the documents where \(i\) > 50. We could also get a range, say 20 < \(i\) <= 30:

```ruby
coll.find("i" => "$gt" => 20, "$lte" => 30).each { |row| puts row }
```

Selecting a subset of fields for a query

Use the :fields option. If you just want fields "a" and "b":

```ruby
coll.find("i" => "$gt" => 50), :fields => ["a", "b"]).each { |row| puts row }
```

Querying with Regular Expressions

Regular expressions can be used to query MongoDB. To find all names that begin with 'a':

```ruby
coll.find({"name" => /^a/)}
```

You can also construct a regular expression dynamically. To match a given search string:

```ruby
search_string = params['search']
# Constructor syntax
coll.find({"name" => Regexp.new(search_string)})
# Literal syntax
coll.find({"name" => /#{search_string}/})
```

Although MongoDB isn't vulnerable to anything like SQL-injection, it may be worth checking the search string for anything malicious.

Creating An Index

MongoDB supports indexes, and they are very easy to add on a collection. To create an index, you specify an index name and an array of field names to be indexed, or a single field name. The following creates an ascending index on the "i" field:

```ruby
# create_index assumes ascending order; see method docs
# for details
coll.create_index("i")
```

To specify complex indexes or a descending index you need to use a slightly more complex syntax - the index specifier must be an Array of [field name, direction] pairs. Directions should be specified as Mongo::ASCENDING or Mongo::DESCENDING:

```ruby
# explicit "ascending"
coll.create_index(["i", Mongo::ASCENDING])
```

Creating and querying on a geospatial index

First, create the index on a field containing long-lat values:
people.create_index(["loc", Mongo::GEO2D]])

Then get a list of the twenty locations nearest to the point 50, 50:

people.find({"loc" => {"$near" => [50, 50]}}, {:limit => 20}).each |p| puts p.inspect

Getting a List of Indexes on a Collection

You can get a list of the indexes on a collection using `coll.index_information()`.

Database Administration

A database can have one of three profiling levels: off (:off), slow queries only (:slow_only), or all (:all). To see the database level:

```ruby
puts db.profiling_level  #=> off (the symbol :off printed as a string)
db.profiling_level = :slow_only
```

Validating a collection will return an interesting hash if all is well or raise an exception if there is a problem.

```ruby
p db.validate_collection('coll_name')
```

Replica Sets in Ruby

⚠️ Redirection Notice
This page should redirect to [http://api.mongodb.org/ruby/current/file.REPLICA_SETS.html](http://api.mongodb.org/ruby/current/file.REPLICA_SETS.html).

Here follow a few considerations for those using the Ruby driver with MongoDB and replica sets.

- Setup
- Connection Failures
- Recovery
- Testing
- Further Reading

Setup

First, make sure that you've configured and initialized a replica set.

Connecting to a replica set from the Ruby driver is easy. If you only want to specify a single node, simply pass that node to `Connection.new`:

```ruby
@connection = Connection.new('foo.local', 27017)
```

If you want to pass in multiple seed nodes, use `Connection.multi`:

```ruby
@connection = Connection.multi([['n1.mydb.net', 27017], ['n2.mydb.net', 27017], ['n3.mydb.net', 27017]])
```
In both cases, the driver will attempt to connect to a master node and, when found, will merge any other known members of the replica set into the seed list.

**Connection Failures**

Imagine that our master node goes offline. How will the driver respond?

At first, the driver will try to send operations to what was the master node. These operations will fail, and the driver will raise a `ConnectionFailure` exception. It then becomes the client's responsibility to decide how to handle this.

If the client decides to retry, it's not guaranteed that another member of the replica set will have been promoted to master right away, so it's still possible that the driver will raise another `ConnectionFailure`. However, once a member has been promoted to master, typically within a few seconds, subsequent operations will succeed.

The driver will essentially cycle through all known seed addresses until a node identifies itself as master.

**Recovery**

Driver users may wish to wrap their database calls with failure recovery code. Here's one possibility:

```ruby
# Ensure retry upon failure
def rescue_connection_failure(max_retries=5)
  success = false
  retries = 0
  while !success
    begin
      yield
      success = true
    rescue Mongo::ConnectionFailure => ex
      retries += 1
      raise ex
      retry if retries >= max_retries
      sleep(1)
    end
  end
end
end

# Wrapping a call to #count()
rescue_connection_failure do
  @db.collection('users').count()
end
```

Of course, the proper way to handle connection failures will always depend on the individual application. We encourage object-mapper and application developers to publish any promising results.

**Testing**

The Ruby driver (>= 1.0.6) includes some unit tests for verifying replica set behavior. They reside in `tests/replica_sets`. You can run them individually with the following rake tasks:

```
rake test:replica_set_count
rake test:replica_set_insert
rake test:pooled_replica_set_insert
rake test:replica_set_query
```

Make sure you have a replica set running on localhost before trying to run these tests.

**GridFS in Ruby**
GridFS, which stands for "Grid File Store," is a specification for storing large files in MongoDB. It works by dividing a file into manageable chunks and storing each of those chunks as a separate document. GridFS requires two collections to achieve this: one collection stores each file’s metadata (e.g., name, size, etc.) and another stores the chunks themselves. If you’re interested in more details, check out the GridFS Specification.

Prior to version 0.19, the MongoDB Ruby driver implemented GridFS using the GridFS::GridStore class. This class has been deprecated in favor of two new classes: Grid and GridFileSystem. These classes have a much simpler interface, and the rewrite has resulted in a significant speed improvement. **Reads are over twice as fast, and write speed has been increased fourfold.** 0.19 is thus a worthwhile upgrade.

- **The Grid class**
  - Saving files
  - File metadata
  - Safe mode
  - Deleting files
- **The GridFileSystem class**
  - Saving files
  - Deleting files
  - Metadata and safe mode
- **Advanced Users**

**The Grid class**

The Grid class represents the core GridFS implementation. Grid gives you a simple file store, keyed on a unique ID. This means that duplicate filenames aren’t a problem. To use the Grid class, first make sure you have a database, and then instantiate a Grid:

```ruby
@db = Mongo::Connection.new.db('social_site')
@grid = Grid.new(@db)
```

**Saving files**

Once you have a Grid object, you can start saving data to it. The data can be either a string or an IO-like object that responds to a #read method:

```ruby
# Saving string data
id = @grid.put("here's some string / binary data")

# Saving IO data and including the optional filename
image = File.open("me.jpg")
id2 = @grid.put(image, :filename => "me.jpg")
```

Grid#put returns an object id, which you can use to retrieve the file:

```ruby
# Get the string we saved
file = @grid.get(id)

# Get the file we saved
image = @grid.get(id2)
```

**File metadata**

There are accessors for the various file attributes:
image.filename
⇒ "me.jpg"

image.content_type
⇒ "image/jpeg"

image.file_length
⇒ 502357

image.upload_date
⇒ Mon Mar 01 16:18:30 UTC 2010

# Read all the image's data at once
image.read

# Read the first 100k bytes of the image
image.read(100 * 1024)

When putting a file, you can set many of these attributes and write arbitrary metadata:

```ruby
# Saving IO data
file = File.open("me.jpg")
id2 = @grid.put(file,
  :filename => "my-avatar.jpg",
  :content_type => "application/jpg",
  :_id => 'a-unique-id-to-use-in-lieu-of-a-random-one',
  :chunk_size => 100 * 1024,
  :metadata => {'description' => "taken after a game of ultimate")
```

Safe mode

A kind of safe mode is built into the GridFS specification. When you save a file, and MD5 hash is created on the server. If you save the file in safe mode, an MD5 will be created on the client for comparison with the server version. If the two hashes don't match, an exception will be raised.

```ruby
image = File.open("me.jpg")
id2 = @grid.put(image, "my-avatar.jpg", :safe => true)
```

Deleting files

Deleting a file is as simple as providing the id:

```ruby
@grid.delete(id2)
```

The GridFileSystem class

GridFileSystem is a light emulation of a file system and therefore has a couple of unique properties. The first is that filenames are assumed to be unique. The second, a consequence of the first, is that files are versioned. To see what this means, let's create a GridFileSystem instance:

Saving files

```ruby
@db = Mongo::Connection.new.db("social_site")
@fs = GridFileSystem.new(@db)
```

Now suppose we want to save the file 'me.jpg.' This is easily done using a filesystem-like API:
We can then retrieve the file by filename:

```ruby
image = @fs.open("me.jpg", "r") { |f| f.read }
```

No problems there. But what if we need to replace the file? That too is straightforward:

```ruby
image = File.open("me-dancing.jpg")
@fs.open("me.jpg", "w") do |f|
  f.write image
end
```

But a couple things need to be kept in mind. First is that the original 'me.jpg' will be available until the new 'me.jpg' saves. From then on, calls to the #open method will always return the most recently saved version of a file. But, and this the second point, old versions of the file won’t be deleted. So if you’re going to be rewriting files often, you could end up with a lot of old versions piling up. One solution to this is to use the :delete_old options when writing a file:

```ruby
image = File.open("me-dancing.jpg")
@fs.open("me.jpg", "w", :delete_old => true) do |f|
  f.write image
end
```

This will delete all but the latest version of the file.

**Deleting files**

When you delete a file by name, you delete all versions of that file:

```ruby
@fs.delete("me.jpg")
```

**Metadata and safe mode**

All of the options for storing metadata and saving in safe mode are available for the GridFileSystem class:

```ruby
image = File.open("me.jpg")
@fs.open('my-avatar.jpg', w, :content_type => "application/jpg",
        :metadata => {?description" => "taken on 3/1/2010 after a game of ultimate"},
        :_id => 'a-unique-id-to-use-instead-of-the-automatically-generated-one',
        :safe => true) { |f| f.write image }
```

**Advanced Users**

Astute code readers will notice that the Grid and GridFileSystem classes are merely thin wrappers around an underlying GridIO class. This means that it’s easy to customize the GridFS implementation presented here; just use GridIO for all the low-level work, and build the API you need in an external manager class similar to Grid or GridFileSystem.

**Rails - Getting Started**
Using Rails 3? See Rails 3 - Getting Started

This tutorial describes how to set up a simple Rails application with MongoDB, using MongoMapper as an object mapper. We assume you're using Rails versions prior to 3.0.

- Configuration
- Testing
- Coding

Using a Rails Template
All of the configuration steps listed below, and more, are encapsulated in this Rails template (raw version), based on a similar one by Ben Scofield. You can create your project with the template as follows:

```shell
rails project_name -m "http://gist.github.com/219223.txt"
```

Be sure to replace `project_name` with the name of your project.

If you want to set up your project manually, read on.

**Configuration**

1. We need to tell MongoMapper which database we'll be using. Save the following to `config/initializers/database.rb`:

   ```ruby
   MongoMapper.database = "db_name-#{Rails.env}"
   ```

   Replace `db_name` with whatever name you want to give the database. The `Rails.env` variable will ensure that a different database is used for each environment.

2. If you're using Passenger, add this code to `config/initializers/database.rb`.

   ```ruby
   if defined?(PhusionPassenger)
     PhusionPassenger.on_event(:starting_worker_process) do |forked|
       MongoMapper.connection.connect_to_master if forked
     end
   end
   ```

3. Clean out `config/database.yml`. This file should be blank, as we're not connecting to the database in the traditional way.

4. Remove ActiveRecord from `environment.rb`.

   ```ruby
   config.frameworks -= [:active_record]
   ```

5. Add MongoMapper to the environment. This can be done by opening `config/environment.rb` and adding the line:

   ```ruby
   config.gem 'mongo_mapper'
   ```

   Once you've done this, you can install the gem in the project by running:

   ```shell
   rake gems:install
   rake gems:unpack
   ```

**Testing**

It's important to keep in mind that with MongoDB, we cannot wrap test cases in transactions. One possible work-around is to invoke a teardown method after each test case to clear out the database.

To automate this, I've found it effective to modify `ActiveSupport::TestCase` with the code below.
This way, all test classes will automatically invoke the teardown method. In the example above, the teardown method clears each collection. We might also choose to drop each collection or drop the database as a whole, but this would be considerably more expensive and is only necessary if our tests manipulate indexes.

Usually, this code is added in `test/test_helper.rb`. See the aforementioned rails template for specifics.

**Coding**

If you've followed the foregoing steps (or if you've created your Rails with the provided template), then you're ready to start coding. For help on that, you can read about modeling your domain in Rails.

**Rails 3 - Getting Started**

It's not difficult to use MongoDB with Rails 3. Most of it comes down to making sure that you're not loading ActiveRecord and understanding how to use Bundler, the new Ruby dependency manager.

- Install the Rails 3
- Configure your application
- Bundle and Initialize
  - Bundling
  - Initializing
- Running Tests
- Conclusion

**Install the Rails 3**

If you haven't done so already, install Rails 3.

```ruby
# Use sudo if your setup requires it
gem install rails
```

**Configure your application**

The important thing here is to avoid loading ActiveRecord. One way to do this is with the `--skip-active-record` switch. So you'd create your app skeleton like so:

```bash
rails new my_app --skip-active-record
```

Alternatively, if you've already created your app (or just want to know what this actually does), have a look at `config/application.rb` and change the first lines from this:

```ruby
require "rails/all"
```

to this:
require "action_controller/railtie"
require "action_mailer/railtie"
require "active_resource/railtie"
require "rails/test_unit/railtie"

It’s also important to make sure that the reference to active_record in the generator block is commented out:

```ruby
# Configure generators values. Many other options are available, be sure to check the documentation.
# config.generators do |g|
#   g.orm             :active_record
#   g.template_engine :erb
#   g.test_framework  :test_unit, :fixture => true
# end
```

As of this writing, it’s commented out by default, so you probably won’t have to change anything here.

**Bundle and Initialize**

The final step involves bundling any gems you’ll need and then creating an initializer for connecting to the database.

**Bundling**

Edit Gemfile, located in the Rails root directory. By default, our Gemfile will only load Rails:

```ruby
gem "rails", "3.0.0"
```

Normally, using MongoDB will simply mean adding whichever OM framework you want to work with, as these will require the "mongo" gem by default.

```ruby
# Edit this Gemfile to bundle your application's dependencies.
source 'http://gemcutter.org'
gem "rails", "3.0.0"
gem "mongo_mapper"
```

However, there’s currently an issue with loading bson_ext, as the current gemspec isn’t compatible with the way Bundler works. We’ll be fixing that soon; just pay attention to this issue.

In the meantime, you can use the following work-around:

```ruby
# Edit this Gemfile to bundle your application's dependencies.
require 'rubygems'
require 'mongo'
source 'http://gemcutter.org'
gem "rails", "3.0.0"
gem "mongo_mapper"
```

Requiring rubygems and mongo before running the gem command will ensure that bson_ext is loaded. If you’d rather not load rubygems, just make sure that both mongo and bson_ext are in your load path when you require mongo.

Once you’ve configured your Gemfile, run the bundle installer:
Initializing

Last item is to create an initializer to connect to MongoDB. Create a Ruby file in config/initializers. You can give it any name you want; here we’ll call it config/initializers/mongo.rb:

```ruby
MongoMapper.connection = Mongo::Connection.new('localhost', 27017)
MongoMapper.database = "#{myapp-#{Rails.env}}"

if defined?(PhusionPassenger)
  PhusionPassenger.on_event(:starting_worker_process) do |forked|
    MongoMapper.connection.connect if forked
  end
end
```

Running Tests

A slight modification is required to get rake test working (thanks to John P. Wood). Create a file lib/tasks/mongo.rake containing the following:

```ruby
namespace :db do
  namespace :test do
    task :prepare do
      # Stub out MongoDB for tests
    end
  end
end
```

Now the various rake test tasks will run properly. See John’s post for more details.

Conclusion

That should be all. You can now start creating models based on whichever OM you’ve installed.

MongoDB Data Modeling and Rails

This tutorial discusses the development of a web application on Rails and MongoDB. MongoMapper will serve as our object mapper. The goal is to provide some insight into the design choices required for building on MongoDB. To that end, we’ll be constructing a simple but non-trivial social news application. The source code for newsmonger is available on github for those wishing to dive right in.

- Modeling Stories
- Caching to Avoid N+1
- A Note on Denormalization
- Fields as arrays
- Atomic Updates
- Modeling Comments
  - Linear, Embedded Comments
  - Nested, Embedded Comments
  - Comment collections
- Unfinished business

Assuming you’ve configured your application to work with MongoMapper, let’s start thinking about the data model.

Modeling Stories

A news application relies on stories at its core, so we’ll start with a Story model:
class Story
  include MongoMapper::Document

  key :title, String
  key :url, String
  key :slug, String
  key :voters, Array
  key :votes, Integer, default: 0
  key :relevance, Integer, default: 0

  # Cached values.
  key :comment_count, Integer, default: 0
  key :username, String

  # Note this: ids are of class ObjectId.
  key :user_id, ObjectId

  timestamps!

  # Relationships.
  belongs_to :user

  # Validations.
  validates_presence_of :title, :url, :user_id
end

Obviously, a story needs a title, url, and user_id, and should belong to a user. These are self-explanatory.

Caching to Avoid N+1

When we display our list of stories, we'll need to show the name of the user who posted the story. If we were using a relational database, we could perform a join on users and stores, and get all our objects in a single query. But MongoDB does not support joins and so, at times, requires a bit of denormalization. Here, this means caching the 'username' attribute.

A Note on Denormalization

Relational purists may be feeling uneasy already, as if we were violating some universal law. But let's bear in mind that MongoDB collections are not equivalent to relational tables; each serves a unique design objective. A normalized table provides an atomic, isolated chunk of data. A document, however, more closely represents an object as a whole. In the case of a social news site, it can be argued that a username is intrinsic to the story being posted.

What about updates to the username? It's true that such updates will be expensive; happily, in this case, they'll be rare. The read savings achieved in denormalizing will surely outweigh the costs of the occasional update. Alas, this is not hard and fast rule: ultimately, developers must evaluate their applications for the appropriate level of normalization.

Fields as arrays

With a relational database, even trivial relationships are blown out into multiple tables. Consider the votes a story receives. We need a way of recording which users have voted on which stories. The standard way of handling this would involve creating a table, 'votes', with each row referencing user_id and story_id.

With a document database, it makes more sense to store those votes as an array of user ids, as we do here with the 'voters' key.

For fast lookups, we can create an index on this field. In the MongoDB shell:

    db.stories.ensureIndex('voters');

Or, using MongoMapper, we can specify the index in config/initializers/database.rb:

    Story.ensure_index(:voters)

To find all the stories voted on by a given user:

    Story.all(:conditions => {:votes => @user.id})
Atomic Updates

Storing the `voters` array in the `Story` class also allows us to take advantage of atomic updates. What this means here is that, when a user votes on a story, we can:

1. ensure that the voter hasn't voted yet, and, if not,
2. increment the number of votes and
3. add the new voter to the array.

MongoDB's query and update features allows us to perform all three actions in a single operation. Here's what that would look like from the shell:

```mongodb
// Assume that story_id and user_id represent real story and user ids.
db.stories.update({ _id: story_id, voters: { $ne: user_id } },
                  { $inc: { votes: 1 }, $push: { voters: user_id } });
```

What this says is "get me a story with the given id whose `voters` array does not contain the given user id and, if you find such a story, perform two atomic updates: first, increment `votes` by 1 and then push the user id onto the `voters` array."

This operation highly efficient; it's also reliable. The one caveat is that, because update operations are "fire and forget," you won't get a response from the server. But in most cases, this should be a non-issue.

A MongoMapper implementation of the same update would look like this:

```ruby
def self.upvote(story_id, user_id)
  collection.update({ '_id' => story_id, 'voters' => { '$ne' => user_id } },
                    { '$inc' => { 'votes' => 1 }, '$push' => { 'voters' => user_id } })
end
```

Modeling Comments

In a relational database, comments are usually given their own table, related by foreign key to some parent table. This approach is occasionally necessary in MongoDB; however, it's always best to try to embed first, as this will achieve greater query efficiency.

Linear, Embedded Comments

Linear, non-threaded comments should be embedded. Here are the most basic MongoMapper classes to implement such a structure:

```ruby
class Story
  include MongoMapper::Document
  many :comments
end

class Comment
  include MongoMapper::EmbeddedDocument
  key :body, String
  belongs_to :story
end
```

If we were using the Ruby driver alone, we could save our structure like so:

```ruby
@stories = @db.collection('stories')
@document = { :title => "MongoDB on Rails", :comments => [ { :body => "Revelatory! Loved it!", :username => "Matz" } ] }
@stories.save(@document)
```

Essentially, comments are represented as an array of objects within a story document. This simple structure should be used for any one-to-many
relationship where the many items are linear.

**Nested, Embedded Comments**

But what if we’re building threaded comments? An admittedly more complicated problem, two solutions will be presented here. The first is to represent the tree structure in the nesting of the comments themselves. This might be achieved using the Ruby driver as follows:

```ruby
@stories  = @db.collection('stories')
@document = {:title => "MongoDB on Rails",
            :comments => [{:body => "Revelatory! Loved it!",
                :username => "Matz",
                :comments => [{:body => "Agreed.",
                                :username => "rubydev29"
                       }]
              }
              ]

@stories.save(@document)
```

Representing this structure using MongoMapper would be tricky, requiring a number of custom mods.

But this structure has a number of benefits. The nesting is captured in the document itself (this is, in fact, how Business Insider represents comments). And this schema is highly performant, since we can get the story, and all of its comments, in a single query, with no application-side processing for constructing the tree.

One drawback is that alternative views of the comment tree require some significant reorganizing.

**Comment collections**

We can also represent comments as their own collection. Relative to the other options, this incurs a small performance penalty while granting us the greatest flexibility. The tree structure can be represented by storing the unique path for each leaf (see Mathias’s original post on the idea). Here are the relevant sections of this model:

```ruby
class Comment
  include MongoMapper::Document

  key :body,       String
  key :depth,      Integer, :default => 0
  key :path,       String, :default => ""

  # Note: we're intentionally storing parent_id as a string
  key :parent_id,  String
  key :story_id,   ObjectId

timestamps!

  # Relationships.
  belongs_to :story

  # Callbacks.
  after_create :set_path

  private

  # Store the comment's path.
  def set_path
    unless self.parent_id.blank?
      parent    = Comment.find(self.parent_id)
      self.story_id = parent.story_id
      self.depth    = parent.depth + 1
      self.path     = parent.path + ":" + parent.id
    end
    save
  end

end
```

The path ends up being a string of object ids. This makes it easier to display our comments nested, with each level in order of karma or votes. If we specify an index on story_id, path, and votes, the database can handle half the work of getting our comments in nested, sorted order.
The rest of the work can be accomplished with a couple grouping methods, which can be found in the newsmonger source code.

It goes without saying that modeling comments in their own collection also facilitates various site-wide aggregations, including displaying the latest, grouping by user, etc.

**Unfinished business**

Document-oriented data modeling is still young. The fact is, many more applications will need to be built on the document model before we can say anything definitive about best practices. So the foregoing should be taken as suggestions, only. As you discover new patterns, we encourage you to document them, and feel free to let us know about what works (and what doesn't).

Developers working on object mappers and the like are encouraged to implement the best document patterns in their code, and to be wary of recreating relational database models in their apps.

**Ruby External Resources**

There are a number of good resources appearing all over the web for learning about MongoDB and Ruby. A useful selection is listed below. If you know of others, do let us know.

- **Screencasts**
- Presentations
- Articles
- Projects
- Libraries

**Screencasts**

*Introduction to MongoDB - Part I*
An introduction to MongoDB via the MongoDB shell.

*Introduction to MongoDB - Part II*
In this screencast, Joon You teaches how to use the Ruby driver to build a simple Sinatra app.

*Introduction to MongoDB - Part III*
For the final screencast in the series, Joon You introduces MongoMapper and Rails.

*RailsCasts: MongoDB & MongoMapper*
Ryan Bates' RailsCast introducing MongoDB and MongoMapper.

*RailsCasts: Mongoid*
Ryan Bates' RailsCast introducing Mongoid.

**Presentations**

*Introduction to MongoDB (Video)*
Mike Dirolf's introduction to MongoDB at Pivotal Labs, SF.

*MongoDB: A Ruby Document Store that doesn't rhyme with 'Ouch' (Slides)*
Wynn Netherland's introduction to MongoDB with some comparisons to CouchDB.

*MongoDB (is) for Rubyists (Slides)*
Kyle Banker's presentation on why MongoDB is for Rubyists (and all human-oriented programmers).

**Articles**

*Why I Think Mongo is to Databases What Rails was to Frameworks*
What if a key-value store mated with a relational database system?

*Mongo Tips*
John Nunemaker's articles on MongoDB and his Mongo Tips blog.

A series of articles on aggregation with MongoDB and Ruby:
1. *Part I: Introduction of Aggregation in MongoDB*
2. *Part II: MongoDB Grouping Elaborated*
3. *Part III: Introduction to Map-Reduce in MongoDB*

*Does the MongoDB Driver Support Feature X?*
An explanation of how the MongoDB drivers usually automatically support new database features.

**Projects**

Simple Pub/Sub
A very simple pub/sub system.

**Mongo Queue**
An extensible thread safe job/message queueing system that uses mongodb as the persistent storage engine.

**Resque-mongo**
A port of the Github's Resque to MongoDB.

**Mongo Admin**
A Rails plugin for browsing and managing MongoDB data. See the [live demo](#).

**Sinatra Resource**
Resource Oriented Architecture (REST) for Sinatra and MongoMapper.

**Shorty**
A URL-shortener written with Sinatra and the MongoDB Ruby driver.

**NewsMonger**
A simple social news application demonstrating MongoMapper and Rails.

**Data Catalog API**
From Sunlight Labs, a non-trivial application using MongoMapper and Sinatra.

**Watchtower**
An example application using Mustache, MongoDB, and Sinatra.

**Shapado**
A question and answer site similar to Stack Overflow. Live version at [shapado.com](http://shapado.com).

### Libraries

**ActiveExpando**
An extension to ActiveRecord to allow the storage of arbitrary attributes in MongoDB.

**ActsAsTree (MongoMapper)**
ActsAsTree implementation for MongoMapper.

**Machinist adapter (MongoMapper)**
Machinist adapter using MongoMapper.

**Mongo-Delegate**
A delegation library for experimenting with production data without altering it. A quite useful pattern.

**Remarkable Matchers (MongoMapper)**
Testing / Matchers library using MongoMapper.

**OpenIdAuthentication, supporting MongoDB as the datastore**
Brandon Keepers' fork of OpenIdAuthentication supporting MongoDB.

**MongoTree (MongoRecord)**
MongoTree adds parent / child relationships to MongoRecord.

**Merb_MongoMapper**
a plugin for the Merb framework for supporting MongoMapper models.

**Mongolytics (MongoMapper)**
A web analytics tool.

**Rack-GridFS**
A Rack middleware component that creates HTTP endpoints for files stored in GridFS.

### Frequently Asked Questions - Ruby

**Redirection Notice**
This page should redirect to [http://api.mongodb.org/ruby/1.1.5/file.FAQ.html](http://api.mongodb.org/ruby/1.1.5/file.FAQ.html).

This is a list of frequently asked questions about using Ruby with MongoDB. If you have a question you'd like to have answered here, please add it in the comments.

- Can I run [insert command name here] from the Ruby driver?
- Does the Ruby driver support an EXPLAIN command?
I see that BSON supports a symbol type. Does this mean that I can store Ruby symbols in MongoDB?

You can store Ruby symbols in MongoDB, but only as values. BSON specifies that document keys must be strings. So, for instance, you can do this:
@collection = @db['test']

boat_id = @collection.save({:vehicle => :boat})
car_id = @collection.save({"vehicle" => "car"})

@collection.find_one('_id' => boat_id)
{"_id" => ObjectID('4bb372a8238d3b5c8c000001'), "vehicle" => :boat}

@collection.find_one('_id' => car_id)
{"_id" => ObjectID('4bb372a8238d3b5c8c000002'), "vehicle" => "car"}

Notice that the symbol values are returned as expected, but that symbol keys are treated as strings.

Why can't I access random elements within a cursor?

MongoDB cursors are designed for sequentially iterating over a result set, and all the drivers, including the Ruby driver, stick closely to this directive. Internally, a Ruby cursor fetches results in batches by running a MongoDB `getmore` operation. The results are buffered for efficient iteration on the client-side.

What this means is that a cursor is nothing more than a device for returning a result set on a query that's been initiated on the server. Cursors are not containers for result sets. If we allow a cursor to be randomly accessed, then we run into issues regarding the freshness of the data. For instance, if I iterate over a cursor and then want to retrieve the cursor's first element, should a stored copy be returned, or should the cursor re-run the query? If we returned a stored copy, it may not be fresh. And if the the query is re-run, then we're technically dealing with a new cursor.

To avoid those issues, we're saying that anyone who needs flexible access to the results of a query should store those results in an array and then access the data as needed.

Why can't I save an instance of TimeWithZone?

MongoDB stores times in UTC as the number of milliseconds since the epoch. This means that the Ruby driver serializes Ruby Time objects only. While it would certainly be possible to serialize a TimeWithZone, this isn't preferable since the driver would still deserialize to a Time object.

All that said, if necessary, it'd be easy to write a thin wrapper over the driver that would store an extra time zone attribute and handle the serialization/deserialization of TimeWithZone transparently.

I keep getting CURSOR_NOT_FOUND exceptions. What's happening?

The most likely culprit here is that the cursor is timing out on the server. Whenever you issue a query, a cursor is created on the server. Cursors naturally time out after ten minutes, which means that if you happen to be iterating over a cursor for more than ten minutes, you risk a CURSOR_NOT_FOUND exception.

There are two solutions to this problem. You can either:

1. Limit your query. Use some combination of `limit` and `skip` to reduce the total number of query results. This will, obviously, bring down the time it takes to iterate.

2. Turn off the cursor timeout. To do that, invoke `find` with a block, and pass `:timeout => true`:

   ```ruby
   @collection.find({}, :timeout => false) do |cursor|
     cursor.each do |document|
       # Process documents here
     end
   end
   ```

I periodically see connection failures between the driver and MongoDB. Why can't the driver retry the operation automatically?

A connection failure can indicate any number of failure scenarios. Has the server crashed? Are we experiencing a temporary network partition? Is there a bug in our ssh tunnel?

Without further investigation, it's impossible to know exactly what has caused the connection failure. Furthermore, when we do see a connection failure, it's impossible to know how many operations prior to the failure succeeded. Imagine, for instance, that we're using safe mode and we send an `$inc` operation to the server. It's entirely possible that the server has received the `$inc` but failed on the call to `getLastError`. In that case, retrying the operation would result in a double-increment.

Because of the indeterminacy involved, the MongoDB drivers will not retry operations on connection failure. How connection failures should be handled is entirely dependent on the application. Therefore, we leave it to the application developers to make the best decision in this case.
The drivers will reconnect on the subsequent operation.

Basics

- Download the Java Driver
- Tutorial
- API Documentation
- Release Notes

Specific Topics and How-To

- Concurrency
- Saving Objects
- Data Types
- Aggregation Framework
- Read Preferences and Tagging

Third Party Frameworks and Libs

POJO Mappers

- Morphia - Type-Safe Wrapper with DAO/Datastore abstractions
- Mungbean (w/ clojure support)
- Spring MongoDB – Provides Spring users with a familiar data access features including rich POJO mapping.
- DataNucleus JPA/JDO – JPA/JDO wrapper
- lib-mongomapper JavaBean Mapper (No annotations)
- mongo-jackson-mapper Uses jackson (annotations) to map to/from POJOs and has a simple wrapper around DBCollection to simply this.
- Kundera - JPA compliant ORM. Works with multiple datastores.
- Jongo - Query in Java as in Mongo shell (using strings), unmarshall results into Java objects (using Jackson)

Code Generation

- Sculptor - mongodb-based DSL -> Java (code generator)
- GuicyData - DSL -> Java generator with Guice integration
  - Blog Entries

Misc

- MongoDB Asynchronous Java Driver - This driver has been created to ensure maximum utilization of resources on the client, in the network, on the server, and in the developer's IDE.
- log4mongo - a log4j appender
- mongo-java-logging - a Java logging handler
- (Experimental, Type4) JDBC driver
- Metamodel data exploration and querying library
- Mongodb Java REST server based on Jetty

Clojure

- Congo Mongo
- monger
Groovy

- Groovy Tutorial for MongoDB
- MongoDB made more Groovy
- GMongo, a Groovy wrapper to the mongodb Java driver
  - GMongo 0.5 Release Writeup

JavaScript (Rhino)

- MongoDB-Rhino - A toolset to provide full integration between the Rhino JavaScript engine for the JVM and MongoDB. Uses the MongoDB Java driver.

JRuby

- jmongo - A thin ruby wrapper around the mongo-java-driver for vastly better jruby performance.

If there is a project missing here, just add a comment or email the list and we'll add it.

- More Java-related presentations

Java Driver Concurrency

The Java MongoDB driver is thread safe. If you are using in a web serving environment, for example, you should create a single Mongo instance, and you can use it in every request. The Mongo object maintains an internal pool of connections to the database (default pool size of 10). For every request to the DB (find, insert, etc) the java thread will obtain a connection from the pool, execute the operation, and release the connection. This means the connection (socket) used may be different each time.

Additionally in the case of a replica set with slaveOk option turned on, the read operations will be distributed evenly across all slaves. This means that within the same thread, a write followed by a read may be sent to different servers (master then slave). In turn the read operation may not see the data just written since replication is asynchronous. If you want to ensure complete consistency in a "session" (maybe an http request), you would want the driver to use the same socket, which you can achieve by using a "consistent request". Call requestStart() before your operations and requestDone() to release the connection back to the pool:

```java
DB db...;
db.requestStart();
try {
  db.requestEnsureConnection();
  code....
} finally {
  db.requestDone();
}
```

DB and DBCollection are completely thread safe. In fact, they are cached so you get the same instance no matter what.

WriteConcern option for single write operation

Since by default a connection is given back to the pool after each request, you may wonder how calling getLastError() works after a write. You should actually use a write concern like WriteConcern.SAFE instead of calling getLastError() manually. The driver will then call getLastError() before putting the connection back in the pool.
Java - Saving Objects Using DBObject

The Java driver provides a DBObject interface to save custom objects to the database.

For example, suppose one had a class called Tweet that they wanted to save:

```java
public class Tweet implements DBObject {
    /* ... */
}
```

Then you can say:

```java
Tweet myTweet = new Tweet();
myTweet.put("user", userId);
myTweet.put("message", msg);
myTweet.put("date", new Date());
collection.insert(myTweet);
```

When a document is retrieved from the database, it is automatically converted to a DBObject. To convert it to an instance of your class, use `DBCollection.setObjectClass()`:

```java
collection.setObjectClass(Tweet.class);
Tweet myTweet = (Tweet)collection.findOne();
```

If for some reason you wanted to change the message you can simply take that tweet and save it back after updating the field.

```java
tweet myTweet = (Tweet)collection.findOne();
tweet.put("message", newMsg);
collection.save(myTweet);
```
Introduction

This page is a brief overview of working with the MongoDB Java Driver.

For more information about the Java API, please refer to the [online API Documentation for Java Driver](#).

A Quick Tour

Using the Java driver is very simple. First, be sure to include the driver jar `mongo.jar` in your classpath. The following code snippets come from the `examples/QuickTour.java` example code found in the driver.

Making A Connection

To make a connection to a MongoDB, you need to have at the minimum, the name of a database to connect to. The database doesn't have to exist - if it doesn't, MongoDB will create it for you.

Additionally, you can specify the server address and port when connecting. The following example shows three ways to connect to the database `mydb` on the local machine:

```java
import com.mongodb.MongoClient;
import com.mongodb.MongoException;
import com.mongodb.WriteConcern;
import com.mongodb.DB;
import com.mongodb.DBCollection;
import com.mongodb.BasicDBObject;
import com.mongodbDBObject;
import com.mongodb.DBCursor;
import com.mongodb.ServerAddress;
import java.util.Arrays;

MongoClient mongoClient = new MongoClient();
// or
MongoClient mongoClient = new MongoClient("localhost");
// or
MongoClient mongoClient = new MongoClient("localhost", 27017);
// or, to connect to a replica set, supply a seed list of members
MongoClient mongoClient = new MongoClient(Arrays.asList(new ServerAddress("localhost", 27017),
    new ServerAddress("localhost", 27018),
    new ServerAddress("localhost", 27019)));

DB db = m.getDB("mydb");
```

At this point, the `db` object will be a connection to a MongoDB server for the specified database. With it, you can do further operations.

Note: The MongoClient instance actually represents a pool of connections to the database; you will only need one instance of class MongoClient even with multiple threads. See the [concurrency] doc page for more information.

The MongoClient class is designed to be thread safe and shared among threads. Typically you create only 1 instance for a given database cluster and use it across your application. If for some reason you decide to create many MongoClient instances, note that:

- all resource usage limits (max connections, etc) apply per MongoClient instance
- to dispose of an instance, make sure you call `MongoClient.close()` to clean up resources

Note: The MongoClient class is new in version 2.10.0. For releases prior to that, please use the Mongo class instead.
Authentication (Optional)

MongoDB can be run in a secure mode where access to databases is controlled through name and password authentication. When run in this mode, any client application must provide a name and password before doing any operations. In the Java driver, you simply do the following with a MongoClient instance:

```java
MongoClient mongoClient = new MongoClient();
DB db = mongoClient.getDB("test");
boolean auth = db.authenticate(myUserName, myPassword);
```

If the name and password are valid for the database, `auth` will be `true`. Otherwise, it will be `false`. You should look at the MongoDB log for further information if available.

Most users run MongoDB without authentication in a trusted environment.

Getting A List Of Collections

Each database has zero or more collections. You can retrieve a list of them from the `db` (and print out any that are there) :

```java
Set<String> colls = db.getCollectionNames();
for (String s : colls) {
    System.out.println(s);
}
```

and assuming that there are two collections, name and address, in the database, you would see

```
name
address
```

as the output.

Getting A Collection

To get a collection to use, just specify the name of the collection to the `getCollection(String collectionName)` method:

```java
DBCollection coll = db.getCollection("testCollection");
```

Once you have this collection object, you can now do things like insert data, query for data, etc

Setting write concern

As of version 2.10.0, the default write concern is `WriteConcern.ACKNOWLEDGED`, but it can be easily changed:

```java
m.setWriteConcern(WriteConcern.JOURNALED);
```

There are many options for write concern. Additionally, the default write concern can be overridden on the database, collection, and individual update operations. Please consult the API Documentation for details.

Note: Prior to version 2.10.0, the default write concern is `WriteConcern.NORMAL`. Under normal circumstances, clients will typically change this to ensure they are notified of problems writing to the database.

Inserting a Document

Once you have the collection object, you can insert documents into the collection. For example, lets make a little document that in JSON would be represented as
Notice that the above has an "inner" document embedded within it. To do this, we can use the BasicDBObject class to create the document (including the inner document), and then simply insert it into the collection using the insert() method.

```java
coll.insert(doc);
```

**Finding the First Document In A Collection using findOne()**

To show that the document we inserted in the previous step is there, we can do a simple findOne() operation to get the first document in the collection. This method returns a single document (rather than the DBCursor that the find() operation returns), and it's useful for things where there only is one document, or you are only interested in the first. You don't have to deal with the cursor.

```java
DBObject myDoc = coll.findOne();
System.out.println(myDoc);
```

and you should see

```json
{ "_id" : "49902cde5162504500b45c2c" , "name" : "MongoDB" , "type" : "database" , "count" : 1 , "info" : { "x" : 203 , "y" : 102 }}
```

Note the _id element has been added automatically by MongoDB to your document. Remember, MongoDB reserves element names that start with "/" for internal use.

**Adding Multiple Documents**

In order to do more interesting things with queries, let's add multiple simple documents to the collection. These documents will just be

```java
{
 "i" : value
}
```

and we can do this fairly efficiently in a loop

```java
for (int i=0; i < 100; i++) {
 coll.insert(new BasicDBObject("i", i));
}
```

Notice that we can insert documents of different "shapes" into the same collection. This aspect is what we mean when we say that MongoDB is "schema-free"

**Counting Documents in A Collection**

Now that we've inserted 101 documents (the 100 we did in the loop, plus the first one), we can check to see if we have them all using the getCount() method.
System.out.println(coll.getCount());

and it should print 101.

**Using a Cursor to Get All the Documents**

In order to get all the documents in the collection, we will use the `find()` method. The `find()` method returns a `DBCursor` object which allows us to iterate over the set of documents that matched our query. So to query all of the documents and print them out:

```java
DBCursor cursor = coll.find();
try {
    while (cursor.hasNext()) {
        System.out.println(cursor.next());
    }
} finally {
    cursor.close();
}
```

and that should print all 101 documents in the collection.

**Getting A Single Document with A Query**

We can create a query to pass to the `find()` method to get a subset of the documents in our collection. For example, if we wanted to find the document for which the value of the "i" field is 71, we would do the following:

```java
BasicDBObject query = new BasicDBObject("i", 71);
cursor = coll.find(query);
try {
    while (cursor.hasNext()) {
        System.out.println(cursor.next());
    }
} finally {
    cursor.close();
}
```

and it should just print just one document

```javascript
{ "_id" : "49903677516250c1008d624e" , "i" : 71 }
```

You may commonly see examples and documentation in MongoDB which use $ Operators, such as this:

```javascript
db.things.find({j: {$ne: 3}, k: {$gt: 10}});
```

These are represented as regular String keys in the Java driver, using embedded DBObjects:

```java
BasicDBObject query = new BasicDBObject("j", new BasicDBObject("$ne", 3)).
append("k", new BasicDBObject("$gt", 10));
cursor = coll.find(query);
try {
    while (cursor.hasNext()) {
        System.out.println(cursor.next());
    }
} finally {
    cursor.close();
}
Getting A Set of Documents With a Query

We can use the query to get a set of documents from our collection. For example, if we wanted to get all documents where \( i > 50 \), we could write:

```java
query = new BasicDBObject("i", new BasicDBObject("$gt", 50)); // e.g. find all where i > 50

cursor = coll.find(query);

try {
    while (cursor.hasNext()) {
        System.out.println(cursor.next);
    }
} finally {
    cursor.close();
}
```

which should print the documents where \( i > 50 \). We could also get a range, say \( 20 < i \leq 30 \):

```java
query = new BasicDBObject("i", new BasicDBObject("$gt", 20)).append("$lte", 30)); // i.e. 20 < i <= 30

cursor = coll.find(query);

try {
    while (cursor.hasNext()) {
        System.out.println(cursor.next);
    }
} finally {
    cursor.close();
}
```

Creating An Index

MongoDB supports indexes, and they are very easy to add on a collection. To create an index, you just specify the field that should be indexed, and specify if you want the index to be ascending (1) or descending (-1). The following creates an ascending index on the \( i \) field:

```java
coll.createIndex(new BasicDBObject("i", 1)); // create index on "i", ascending
```

Getting a List of Indexes on a Collection

You can get a list of the indexes on a collection:

```java
List<DBObject> list = coll.getIndexInfo();

for (DBObject o : list) {
    System.out.println(o);
}
```

and you should see something like

```json
{
    "name": "i_1",
    "ns": "mydb.testCollection",
    "key": { "i": 1 }
}
```

Quick Tour of the Administrative Functions

Getting A List of Databases

You can get a list of the available databases:
Dropping A Database

You can drop a database by name using a MongoClient instance:

```java
MongoClient mongoClient = new MongoClient();
mongoClient.dropDatabase("myDatabase");
```

Java Types

- **Object Ids**
- **Regular Expressions**
- **Dates/Times**
- **Database References**
- **Binary Data**
- **Timestamp Data**
- **Code Data**
- **Embedded Documents**
- **Arrays**

Object Ids

`com.mongodb.ObjectId` is used to autogenerate unique ids.

```java
ObjectId id = new ObjectId();
ObjectId copy = new ObjectId(id);
```

Regular Expressions

The Java driver uses `java.util.regex.Pattern` for regular expressions.

```java
Pattern john = Pattern.compile("joh?n", CASE_INSENSITIVE);
BasicDBObject query = new BasicDBObject("name", john);
// finds all people with "name" matching /joh?n/i
DBCursor cursor = collection.find(query);
```

Dates/Times

The `java.util.Date` class is used for dates.

```java
Date now = new Date();
BasicDBObject time = new BasicDBObject("ts", now);

collection.save(time);
```

Database References

`com.mongodb.DBRef` can be used to save database references.
DBRef addressRef = new DBRef(db, "foo.bar", address_id);
DBObject address = addressRef.fetch();

DBObject person = BasicDBObjectBuilder.start()
    .add("name", "Fred")
    .add("address", addressRef)
    .get();
collection.save(person);

DBObject fred = collection.findOne();
DBRef addressObj = (DBRef)fred.get("address");
addressObj.fetch();

**Binary Data**

An array of bytes (byte[]) as a value will automatically be wrapped as a Binary type. Additionally the Binary class can be used to represent binary objects, which allows to pick a custom type byte.

**Timestamp Data**

A timestamp is a special object used by Mongo as an ID based on time, represented by a (time in second, incremental id) pair (it is used notably in the replication oplog). A timestamp is represented by the BSONTimestamp class.

**Code Data**

A code object is used to represent JavaScript code, for example when saving executable functions into the system.js collection. The Code and CodeWScope classes are used to represent this data. Note that some methods (like map/reduce) take Strings but wrap them into Code objects in the driver.

**Embedded Documents**

Suppose we have a document that, in JavaScript, looks like:

```javascript
{
    "x": {
        "y": 3
    }
}
```

The equivalent in Java is:

```java
BasicDBObject y = new BasicDBObject("y", 3);
BasicDBObject x = new BasicDBObject("x", y);
```

**Arrays**

Anything that extends List in Java will be saved as an array.

So, if you are trying to represent the JavaScript:

```javascript
{
    "x": [
        1,
        2,
        {"foo": "bar"},
        4
    ]
}
```

you could do:
ArrayList x = new ArrayList();
x.add(1);
x.add(2);
x.add(new BasicDBObject("foo", "bar"));
x.add(4);
BasicDBObject doc = new BasicDBObject("x", x);

Read Preferences and Tagging in The Java Driver

MongoDB’s read preferences and tagging allows application developers to target member nodes within a replica set for read or write operations. Version 2.2 brings several refinements on node tagging that give you greater control over how your data is read or written. Release 2.9.0 of the Java driver has been built in coordination with the release of Mongo 2.2 and provides full access to these newly available preferences and tagging features.

Read Preferences
A read preference provides client applications with control over which nodes of a replica set are used for reads. A client application defines its read preference by selecting one of the five behavioral modes:

- PRIMARY : The default read mode. Read from primary only. Throw an error if primary is unavailable. Cannot be combined with tags.
- PRIMARY PREFERRED : Read from primary if available, otherwise a secondary.
- SECONDARY : Read from a secondary node if available, otherwise error.
- SECONDARY PREFERRED : Read from a secondary if available, otherwise read from the primary.
- NEAREST : Read from any member node from the set of nodes which respond the fastest. The responsiveness of a node is measured with pings. Any node whose ping time is within 15 milliseconds of the node with the lowest ping time is considered near.

Implementation
The Java driver implements MongoDB’s read preferences with the ReadPreference class. Client applications allocate the desired read mode by calling one of ReadPreference’s static factory methods. One factory method exists for each mode.

```java
ReadPreference.primary();
ReadPreference.primaryPreferred();
ReadPreference.secondary();
ReadPreference.secondaryPreferred();
ReadPreference.nearest();
```

The factory method returns a private inner subclass of ReadPreference that implements the correct behavioral mode. The driver’s use of polymorphism in this manner means that your code only needs to interface with the ReadPreference class alone.

element:
Suppose we are developing an application and we prefer operate on strongly consistent data, (i.e. read requests always return the most recent updates of a given document). In this case, the primary node will handle all reads and writes. Now suppose our application must be able to perform reads even if the primary becomes unavailable for some reason. Even though we prefer data consistency we can tolerate eventual consistency when the primary is down. We therefore use the primary preferred mode as our read preference.

```java
ReadPreference preference = ReadPreference.primaryPreferred();
DBCursor cur = new DBCursor(collection, query, null, preference);
```

The Java driver maintains knowledge and state of the replica set by periodically pinging the member nodes and can detect the loss of a member. In this example, the driver will automatically detect the loss of the primary and route the read request to a secondary node, just as we have instructed.

Tags
As of version 2.0 of MongoDB, each node within your replica set can be marked with additional descriptors called tags. Tags can be used to indicate a node’s location, membership in a designated set, or other characteristics. Tags enable your application to read from or write to specific nodes or a set of nodes in a replica set.

As an example, suppose we’re running a replica set of three nodes deployed across three separate data centers. Each of these data centers is in a separate geographic location. We want to ensure that our data will persist in the event of a disaster, so we mark each node with a tag indicating the region where it lives. Our replica set configuration might look similar to this:
Notice the “settings” field in the replication configuration. We've defined a new `getLastErrorModes` object with the key DRSafe. When our client application uses this error mode in a write concern it is instructing the write operation to replicate to at least two regions before completion. Here’s an example in the Java driver:

```java
// create a write concern with the specific getLastErrorMode
WriteConcern concern = new WriteConcern("DRSafe");
// an insert with the custom write concern
coll.insert(newBasicDBObject("name", "simple doc"), concern);
```

By allocating a write concern using the “DRSafe” error mode and passing it in on the insert, we have now ensured that our data has been backed up to two separate regions and will be available should a data center fail.

**Using Tags with Read Preferences**

Continuing with our sample application, we decide that we want to send our read requests to the nearest node to reduce request latency. The Java driver’s read preference API gives a couple of ways of doing this, the easiest is to simply use the nearest mode.

```java
DBObject query = newBasicDBObject("name", "simple doc")
DBObject result = coll.findOne(query, null, ReadPreference.nearest());
```

By using the nearest mode the driver will automatically send the read to one of a set of nodes with the lowest ping time relative to the client application, (the receiving node could be either a primary or secondary). But suppose our client application can determine where its requests originate. We could have explicitly tagged the read preference to use the datacenter nearest to our location.
Look again at the replica set configuration from above. Each node has been tagged by data center. Let’s say that the current read request is coming from southern California. We can configure this read request to be served by the node living in our Los Angeles data center.

```java
// initialize a properly tagged read preference
ReadPreference tagged_pref =
    ReadPreference.secondaryPreferred(new BasicDBObject("datacenter", "Los Angeles"));

// include the tagged read preference in this request
DBObject result = coll.findOne(new BasicDBObject("name", "simple doc"), null, tagged_pref);
```

Read preferences can also accept multiple tags. Returning to our example application, suppose we want to send our reads either the “Los Angeles” node, or failing to find a healthy member in Los Angeles a node in the “US_West” region.

```java
// read from either LA or US_West
DBObject tagSetOne = new BasicDBObject("datacenter", "Los Angeles");
DBObject tagSetTwo = new BasicDBObject("region", "US_West");

ReadPreference pref =
    ReadPreference.primaryPreferred(tagSetOne, tagSetTwo);
```

In this example, the driver looks first for a member tagged with datacenter “Los Angeles”. If it cannot find an available member, the driver will look for a member tagged with region of “US West”. You may use a tag set to define a set of required tags a member node must have to be used for the read. For example:

```java
// read from either LA or US_West
DBObject tagSetOne = new BasicDBObject("datacenter", "Los Angeles");
tagSetOne.put("rack", 1);
DBObject tagSetTwo = new BasicDBObject("region", "US_West");

ReadPreference pref =
    ReadPreference.primaryPreferred(tagSetOne, tagSetTwo);
```

The difference being the driver is looking for a node that is tagged with both data center Los Angeles and on rack 1, or a node that is in region “US_West”.

You can set the Read Preference at the operation, collection, DB, Mongo, MongoOptions, or MongoURI level, and the preference will be inherited similar to the way slaveOk and write concern are. Read preferences work with any server version that supports replica sets (1.6 and up). Tagged read preferences work with any version that supports tagging (2.0 and up). However, tagging will only work on a sharded cluster if you are connecting to a mongos running 2.2 or above.

**Replica Set Semantics**

The MongoDB Java driver handles failover in replicated setups with tunable levels of transparency to the user. By default, a Mongo connection object will ignore failures of secondaries, and only reads will throw MongoExceptions when the primary node is unreachable.

The level of exception reporting is tunable however, using a specific WriteConcern; you can set this on the Mongo/DB/Collection/Method level. Several levels are included as static options:

- **WriteConcern.NONE**: No exceptions thrown.
- **WriteConcern.NORMAL**: Exceptions are only thrown when the primary node is unreachable for a read, or the full replica set is unreachable.
- **WriteConcern.SAFE**: Same as the above, but exceptions thrown when there is a server error on writes or reads. Calls `getLastError()`.
- **WriteConcern.REPLICAS_SAFE**: Tries to write to two separate nodes. Same as the above, but will throw an exception if two writes are not possible.
- **WriteConcern.FSYNC_SAFE**: Same as **WriteConcern.SAFE**, but also waits for write to be written to disk.

**Additional errors may appear in the log files, these are for reporting purposes and logged based on the logging settings.**

Sample code is provided which illustrates some of these options. To quickly initialize a sample replica set, you can use the mongo shell:
Java client code demonstrating error handling is available:

**Using The Aggregation Framework with The Java Driver**

Release 2.2.0 of MongoDB introduces the aggregation framework. Designed to be both performant and easy to use, the aggregation framework calculates aggregate values, (such as counts, totals and averages), without the need for complex map-reduce operations. The aggregation framework is both multithreaded and written in C++, thus it executes natively across nodes.

Aggregation tasks are built around the concept of the aggregation pipeline. Just as UNIX-like shells use the pipe operator `|` to connect a series of command-line operations together, the aggregation framework passes documents through a pipeline of operations which transform these objects as they go. Version 2.9.0 of the Java driver provides a new helper method, `DBCollection.aggregate()` which can be used to create aggregation tasks.

Let's use a simple example to demonstrate how the aggregation helper works. Suppose I am using MongoDB to store my employee’s travel expenses. I've created a collection named “expenses”, which store individual expenses by employee and by department. Here's a sample document:

```json
{
    "_id": ObjectId("503d5024ff9038cdbfcc9da4"),
    "employee": 61,
    "department": "Sales",
    "amount": 77,
    "type": "airfare"
}
```

I am auditing three departments: Sales, Engineering and Human Resources. I want to calculate each department's average spend on airfare. I'd like to use the Aggregation Framework for the audit, so I think of the operation in terms of a pipeline:

**Pipeline Operations**

1. Match documents where `type = airfare` into the pipeline
2. Pass only the `department` and `amount` fields through the pipeline
3. Average the expense `amount`, grouped by department

I will use the aggregation operators `$match`, `$project` and `$group` to perform each operation. Individual aggregation operations can be expressed as JSON objects, so I can think of my pipeline as:
I use the Java Driver’s aggregation helper to build out this pipeline in my application. Let’s take a look at the aggregate() method signature.

```java
public AggregationOutput aggregate(DBObject firstOp, DBObject ... additionalOps)
```

The aggregate method uses Java varargs and accepts arbitrary number of DBObjects as parameters. These DBObjects represent aggregation operations, which will be chained together by the helper method to form the aggregation pipeline. Callers of the aggregate method must pass at least one aggregation operation. Here’s the Java code we’ll use to perform the aggregation task:

```java
// create our pipeline operations, first with the $match
DBObject match = new BasicDBObject("$match", new BasicDBObject("type", "airfare") );

// build the $projection operation
DBObject fields = new BasicDBObject("department", 1);
fields.put("amount", 1);
fields.put("_id", 0);
DBObject project = new BasicDBObject("$project", fields);

// Now the $group operation
DBObject groupFields = new BasicDBObject( "_id", "$department");
groupFields.put("average", new BasicDBObject( "$avg", "$amount"));
DBObject group = new BasicDBObject("$group", groupFields);

// run aggregation
AggregationOutput output = collection.aggregate( match, project, group );
```

Aggregations are executed as database commands in MongoDB. These commands embed the results of the aggregation task in an object that also contains additional information about how the command was executed. The return value of aggregate() is an instance of the AggregationOutput class, which provides assessors to this information.

```java
public Iterable<DBObject> results()
public CommandResult getCommandResult
public DObject getCommand()
```

Let’s take a look at the results of my audit:
System.out.println(output.getCommandResult());

{
  "serverUsed" : "/127.0.0.1:27017",
  "result" : [
  {"_id" : "Human Resources", "average" : 74.9173537190083},
  {"_id" : "Sales", "average" : 72.30275229357798},
  {"_id" : "Engineering", "average" : 74.1}
  ],
  "ok" : 1.0
}

C++ Language Center

A C++ driver is available for communicating with the MongoDB. As the database is written in C++, the driver actually uses some core MongoDB code -- this is the same driver that the database uses itself for replication.

The driver has been compiled successfully on Linux, OS X, Windows, and Solaris.

- Downloading the Driver
- Compiling and Linking
- MongoDB C++ Client Tutorial
- API Documentation
- Using BSON from C++
- SQL to C++ Mapping Chart
- HOWTO
  - Connecting
  - getLastError
  - Tailable Cursors
  - BSON Arrays in C++

- Mongo Database and C++ Driver Source Code (at github). See the client subdirectory for client driver related files.

Additional Notes

- The Building documentation covers compiling the entire database, but some of the notes there may be helpful for compiling client applications too.
- There is also a pure C driver for MongoDB. For true C++ apps we recommend using the C++ driver.

BSON Arrays in C++
using namespace mongo;
using namespace bson;

bo an_obj;

/** transform a BSON array into a vector of BSONElements.
we match array # positions with their vector position, and ignore
any fields with non-numeric field names. */
vector<be> a = an_obj[0x0].Array();

be array = an_obj[0x0];
assert( array.isABSONObj() );
assert( array.type() == Array );

// Use BSON_ARRAY macro like BSON macro, but without keys
BSONArray arr = BSON_ARRAY( "hello" << 1 << BSON( "foo" << BSON_ARRAY( "bar" << "baz" << "qux" ) ) );

// BSONArrayBuilder can be used to build arrays without the macro
BSONArrayBuilder b;
b.append(1).append(2).arr();

/** add all elements of the object to the specified vector * /
bo myarray = an_obj[0x0].Obj();
vector<be> v;
myarray.elems(v);
list<be> L;
myarray.elems(L);

/** add all values of the object to the specified collection. If type mismatches,
    exception.
    template <class T>
    void Vals(vector<T> & const);
    template <class T>
    void vals(list<T> & const);
*/

/** add all values of the object to the specified collection. If type mismatches, skip.
    template <class T>
    void Vals(vector<T> & const);
    template <class T>
    void vals(list<T> & const);
*/

---

C++ BSON Library

- Standalone Usage
- API Docs
- Short Class Names

The MongoDB C++ driver library includes a bson package that implements the BSON specification (see [http://www.bsonspec.org/](http://www.bsonspec.org/)). This library can be used standalone for object serialization and deserialization even when one is not using MongoDB at all.

Include `bson/bson.h` or `db/jsobj.h` in your application (not both). `bson.h` is new and may not work in some situations, was is good for light header-only usage of BSON (see the bsondemo.cpp example).

Key classes:

- `mongo::BSONObj` (aka `bson::bo`) a BSON object
- `mongo::BSONElement` (`bson::be`) a single element in a bson object. This is a key and a value.
- `mongo::BSONObjBuilder` (`bson::bob`) used to make BSON objects
Let's now create a BSON "person" object which contains name and age. We might invoke:

```cpp
BSONObjBuilder b;
b.append("name", "Joe");
b.append("age", 33);
BSONObj p = b.obj();
```

Or more concisely:

```cpp
BSONObj p = BSONObjBuilder().append("name", "Joe").append("age", 33).obj();
```

We can also create objects with a stream-oriented syntax:

```cpp
BSONObjBuilder b;
b << "name" << "Joe" << "age" << 33;
BSONObj p = b.obj();
```

The macro BSON lets us be even more compact:

```cpp
BSONObj p = BSON( "name" << "Joe" << "age" << 33 );
```

Use the GENOID helper to add an object id to your object. The server will add an _id automatically if it is not included explicitly.

```cpp
BSONObj p = BSON( GENOID << "name" << "Joe" << "age" << 33 );
// result is: { _id : ..., name : "Joe", age : 33 }
```

Standalone Usage

You can use the C++ BSON library without MongoDB. Most BSON methods under the bson/ directory are header-only. They require boost, but headers only.

See the bsondemo.cpp example at github.com.

API Docs

- [http://api.mongodb.org/cpp/plusplus/](http://api.mongodb.org/cpp/plusplus/)

Short Class Names

Add

```cpp
using namespace bson;
```

to your code to use the following shorter more C++ style names for the BSON classes:
// from bsonelement.h
namespace bson {
  typedef mongo::BSONElement be;
  typedef mongo::BSONObj bo;
  typedef mongo::BSONObjBuilder bob;
}

(Or one could use bson::bo fully qualified for example).

Also available is bo::iterator as a synonym for BSONObjIterator.

## C++ Driver Compiling and Linking

- **Linux**
  - Using the prebuilt library
  - Using mongo_client_lib.cpp instead of a library

- **Windows**
  - Windows Troubleshooting

The C++ driver is included in the MongoDB server source repository, and can also be downloaded as a separate, "standalone" tarball (see **Downloads**). To compile the "standalone" C++ driver, run the scons command in the top-level directory of the driver sources, e.g.:

```
cd mongo-cxx-driver-nightly/
scons
```

You may wish to compile and link client/simple_client_demo.cpp to verify that everything compiles and links fine.

### Linux

#### Using the prebuilt library

```
$ cd mongo/client
$ g++ simple_client_demo.cpp -lmongoclient -lboost_thread-mt -lboostfilesystem -lboost_program_options
```

#### Using mongo_client_lib.cpp instead of a library

If you have a compatibility problem with the library, include mongo_client_lib.cpp in your project instead. For example:

```
g++ -I .. simple_client_demo.cpp mongo_client_lib.cpp -lboost_thread-mt -lboostfilesystem
```

### Windows

Note: we tend to test MongoDB with Windows using Visual Studio 2010. 2008 works, although you may have to tweak settings in some cases.

Include mongoclient.lib in your application.

To build mongoclient.lib:

```
scons mongoclient
```

Alternatively, include client/mongo_client_lib.cpp in your project.

For Windows, see also:

- bson/bsondemo/bsondemo.vcxproj
- client/examples/simple_client_demo.vcxproj
- Prebuilt Boost Libraries
  - Prebuild Boost Libraries only necessary for versions < 2.1.1
  - Boost 1.49 source is now included directly in version 2.1.1+
• Building with Visual Studio 2010

Other notes for Windows:

• Compile with /MT
• You may wish to define _CRT_SECURE_NO_WARNINGS to avoid warnings on use of strncpy and such by the MongoDB client code.
• Include the WinSock library in your application: Linker.Input.Additional Dependencies - add ws2_32.lib.

Windows Troubleshooting

• error LNK2005: ___ already defined in msvcprt.lib(MSVCP100.dll) libboost_thread-vc100-mt-1_42.lib(thread.obj)
  • The boost library being linked against is expecting a /MT build. If this is a release build, try using /MT instead of /MD for compilation (under Properties.C++.Code Generation).

C++ Driver Download

Driver tarballs

The C++ client library can be found at http://dl.mongodb.org/dl/cxx-driver/.

Note: despite the word ‘linux’ in the filenames, these files are mostly source code and thus should be applicable to all operating systems.

From the server source code

If you have the full MongoDB source code, the driver code is part of it. This is available on github and also on the MongoDB Downloads page.

The full server source is quite large, so the tarballs above may be easier. Also if using the full server source tree, use "scons mongoclient" to build just the client library.

Next: Compiling and Linking

C++ getLastError

• string mongo::DBClientWithCommands::getLastError();
  • Get error result from the last operation on this connection. Empty string if no error.

• BSONObj DBClientWithCommands::getLastErrorDetailed();
  • Get the full last error object. See the getLastError Command page for details.

See client/simple_client_demo.cpp for an example.

    • Full Database Source Driver Build
    • Driver Build
  • Windows
• Compiling
• Writing Client Code
  • Connecting
  • BSON
  • Inserting
  • Querying
  • Indexing
  • Sorting
  • Updating
  • Example
• Further Reading

This document is an introduction to usage of the MongoDB database from a C++ program.

First, install Mongo -- see the Quickstart for details.

Next, you may wish to take a look at the Developer's Tour guide for a language independent look at how to use MongoDB. Also, we suggest
some basic familiarity with the `mongo shell` -- the shell is one's primary database administration tool and is useful for manually inspecting the contents of a database after your C++ program runs.

### Installing the Driver Library and Headers

A good source for general information about setting up a MongoDB development environment on various operating systems is the [building](https://www.mongodb.com/) page.

The normal database distribution used to include the C++ driver, but there were many problems with library version mismatches so now you have to build from source. You can either get the [full source code](https://www.mongodb.com/) for the database and just build the C++ driver or [download the driver](https://www.mongodb.com/) separately and build it.

#### Unix

For Unix, the Mongo driver library is `libmongoclient.a`. For either build, run `scons --help` to see all options.

**Full Database Source Driver Build**

To install the libraries, run:

```
  scons --full install
```

`--full` tells the install target to include the library and header files; by default library and header files are installed in `/usr/local`.

You can use `--prefix` to change the install path: `scons --prefix /opt/mongo --full install`.

In version 2.0, you can also specify `--sharedclient` to build a shared library instead of a statically linked library. This feature is not yet working properly in 2.2, see SERVER-6514.

**Driver Build**

If you download the [driver source code](https://www.mongodb.com/) separately, you can build it by running `scons` (no options).

#### Windows

For more information on Boost setup see the [Building for Windows](https://www.mongodb.com/) page.

**Compiling**

The C++ driver requires the `pcre` and `boost` libraries (with headers) to compile. Be sure they are in your include and lib paths. You can usually install them from your OS's package manager if you don't already have them.

**Writing Client Code**

Note: for brevity, the examples below are simply inline code. In a real application one will define classes for each database object typically.

**Connecting**

Let's make a tutorial.cpp file that connects to the database (see client/examples/tutorial.cpp for full text of the examples below):
```cpp
#include <cstdlib>
#include <iostream>
#include "mongo/client/dbclient.h"

void run() {
    mongo::DBClientConnection c;
    c.connect("localhost");
}

int main() {
    try {
        run();
        std::cout << "connected ok" << std::endl;
    } catch (const mongo::DBException &e) {
        std::cout << "caught " << e.what() << std::endl;
    }
    return EXIT_SUCCESS;
}

If you are using gcc on Linux or OS X, you would compile with something like this, depending on location of your include files and libraries:

```bash
$ g++ tutorial.cpp -pthread -lmongoclient -lboost_thread-mt -lboost_filesystem -lboost_program_options -lboost_system -o tutorial
$ ./tutorial
connected ok
```

⚠️ You may need to append "-mt" to boost_filesystem and boost_program_options. If using a recent boost, "-mt" is not needed anymore.

You may need to use -I and -L to specify the locations of your mongo and boost headers and libraries.

**BSON**

The Mongo database stores data in **BSON** format. BSON is a binary object format that is JSON-like in terms of the data which can be stored (some extensions exist, for example, a Date datatype).

To save data in the database we must create objects of class **BSONObj**. The components of a BSONObj are represented as **BSONElement** objects. We use **BSONObjBuilder** to make BSON objects, and **BSONObjIterator** to enumerate BSON objects.

Let's now create a BSON "person" object which contains name and age. We might invoke:

```cpp
BSONObjBuilder b;
b.append("name", "Joe");
b.append("age", 33);
BSONObj p = b.obj();
```

Or more concisely:

```cpp
BSONObj p = BSONObjBuilder().append("name", "Joe").append("age", 33).obj();
```

We can also create objects with a stream-oriented syntax:

```cpp
BSONObjBuilder b;
b << "name" << "Joe" << "age" << 33;
BSONObj p = b.obj();
```

The macro BSON lets us be even more compact:
Use the GENOID helper to add an object id to your object. The server will add an _id automatically if it is not included explicitly.

```
BSONObj p = BSON(GENOID << "name" << "Joe" << "age" << 33);
```

GENOID should be at the beginning of the generated object. We can do something similar with the non-stream builder syntax:

```
BSONObj p = BSONObjBuilder().genOID().append("name","Joe").append("age",33).obj();
```

Other helpers are listed here.

**Inserting**

We now save our person object in a persons collection in the database:

```
c.insert("tutorial.persons", p);
```

The first parameter to insert is the namespace. tutorial is the database and persons is the collection name.

**Querying**

Let's now fetch all objects from the persons collection, and display them. We'll also show here how to use count().

```
cout << "count:" << c.count("tutorial.persons") << endl;
auto_ptr<DBClientCursor> cursor =
c.query("tutorial.persons", BSONObj());
while (cursor->more()) {
    BSONObj p = cursor->next();
    cout << p.getStringField("name") << endl;
}
```

BSONObj() is an empty BSON object -- it represents {} which indicates an empty query pattern (an empty query is a query for all objects).

We use BSONObj::toString() above to print out information about each object retrieved. BSONObj::toString is a diagnostic function which prints an abbreviated JSON string representation of the object. For full JSON output, use BSONObj::jsonString.

Let's now write a function which prints out the name (only) of all persons in the collection whose age is a given value:

```
void printIfAge(DBClientConnection& c, int age) {
    auto_ptr<DBClientCursor> cursor =
c.query("tutorial.persons", QUERY("age" << age));
    while (cursor->more()) {
        BSONObj p = cursor->next();
        cout << p.getStringField("name") << endl;
    }
}
```

getStringField() is a helper that assumes the "name" field is of type string. To manipulate an element in a more generic fashion we can retrieve the particular BSONElement from the enclosing object:

```
BSONElement name = p["name"];
// or:
//BSONElement name = p.getField("name");
```

See the api docs, and jsobj.h, for more information.

Our query above, written as JSON, is of the form
Queries are BSON objects of a particular format -- in fact, we could have used the BSON() macro above instead of QUERY(). See class Query in dbclient.h for more information on Query objects, and the Sorting section below.

In the mongo shell (which uses javascript), we could invoke:

```javascript
use tutorial;
db.persons.find({age : 33});
```

**Indexing**

Let's suppose we want to have an index on age so that our queries are fast. We would use:

```javascript
c.ensureIndex("tutorial.persons", fromjson("{age:1}\""));
```

The ensureIndex method checks if the index exists; if it does not, it is created. ensureIndex is intelligent and does not repeat transmissions to the server; thus it is safe to call it many times in your code, for example, adjacent to every insert operation.

In the above example we use a new function, fromjson. fromjson converts a JSON string to a BSONObj. This is sometimes a convenient way to specify BSON. Alternatively, we could have written:

```javascript
c.ensureIndex("tutorial.persons", BSON("age" << 1\""));
```

**Sorting**

Let's now make the results from printIfAge sorted alphabetically by name. To do this, we change the query statement from:

```c++
auto_ptr<DBClientCursor> cursor = c.query("tutorial.persons", QUERY("age" << age));
```

to

```c++
to auto_ptr<DBClientCursor> cursor = c.query("tutorial.persons", QUERY("age" << age).sort("name"));
```

Here we have used Query::sort() to add a modifier to our query expression for sorting.

**Updating**

Use the update() method to perform a database update. For example the following update in the mongo shell:

```bash
> use tutorial
> db.persons.update( { name : 'Joe', age : 33 }, ...
    { $inc : { visits : 1 } } )
```

is equivalent to the following C++ code:

```cpp
db.update("tutorial.persons",
    BSON("name" << "Joe" << "age" << 33),
    BSON("$inc" << BSON("visits" << 1)));
```

**Example**

A simple example illustrating usage of BSON arrays and the "$nin" operator is available here.

**Further Reading**
This overview just touches on the basics of using Mongo from C++. There are many more capabilities. For further exploration:

- See the language-independent Developer’s Tour;
- Experiment with the mongo shell;
- Review the doxygen API docs;
- See connecting pooling information in the API docs;
- See GridFS file storage information in the API docs;
- See the HOWTO pages under the C++ Language Center
- Consider getting involved to make the product (either C++ driver, tools, or the database itself) better!

List of helper functions

This is a non-exhaustive list of helper functions for use in the C++ stream syntax. An exhaustive list is here: bsonmisc.h

Typical example of stream syntax:

```cpp
BSONObj p = BSON("name" << "Joe" << "age" << 33);
```

**GENOID** - the server will add an _id automatically if it is not included explicitly.

```cpp
BSONObj p = BSON( GENOID << "name" << "Joe" << "age" << 33 );
// result is: { _id : ..., name : "Joe", age : 33 }
```

**LT,GT,LTE,GTE, NE** - less than, greater than, etc

```cpp
BSONObj p = BSON( "age" << GT << 21 );
// result is: { age : { $gt : 21 } }
```

**DATENOW** - translates to current date

```cpp
BSONObj p = BSON( "created" << DATENOW );
// result is: { created : "2009-10-09 11:41:42" }
```

**MINKEY,MAXKEY**

```cpp
BSONObj p = BSON( "a" << MINKEY);
// result is: { "a" : { "$minKey" : 1 } }
```

**OR**

```cpp
OR(BSON("x" << GT << 7), BSON("y" << LT << 6))
// result is: { $or: [{x: {$gt: 7}}, {y: {$lt: 6}}] }
```

**BSONNULL** - translates to null value (will appear in MongoDB 2.1)

```cpp
BSONObj p = BSON( "name" << "Methuselah" << "age" << BSONNULL );
// result is: { name : "Methuselah", age : null }
```

Connecting

The C++ driver includes several classes for managing collections under the parent class DBClientInterface.

DBClientConnection is our normal connection class for a connection to a single MongoDB database server (or shard manager). Other classes exist for connecting to a replica set.

See http://api.mongodb.org/cplusplus/ for details on each of the above classes.

**SQL to Shell to C++**
MongoDB queries are expressed as JSON (BSON) objects. This quick reference chart shows examples as SQL, Mongo shell syntax, and Mongo C++ driver syntax.

A query expression in MongoDB (and other things, such as an index key pattern) is represented as BSON. In C++ you can use BSONObjBuilder (aka bson::bob) to build BSON objects, or the BSON() macro. The examples below assume a connection c already established:

```c
using namespace bson;
DBClientConnection c;
c.connect("somehost");
```

Several of the C++ driver methods throw `mongo::DBException`, so you will want a try/catch statement as some level in your program. Also be sure to call `c.getLastError()` after writes to check the error code.

<table>

</tbody>
</table>
SELECT COUNT(*)
FROM users
WHERE AGE > 30

unsigned long long n =
c.count("mydb.users",
BSON("age"<<GT<<30));

UPDATE users
SET a=a+2
WHERE b='q'

c.update("mydb.users",
QUERY("b"<<"q"),
BSON("$inc"<<BSON("a"<<2)),
false, true);
// then optionally:
string err =
c.getLastError();
bool ok = err.empty();

DELETE FROM
users WHERE
z="abc"

c.remove("mydb.users",
QUERY("z"<<"abc"));
// then optionally:
string err =
c.getLastError();
The Perl driver is available through CPAN as the package MongoDB. It should build cleanly on *NIX and Windows (via Strawberry Perl). It is also available as an ActivePerl module.

**Manual (Non-CPAN) Installation**

If you would like to try the latest code or are contributing to the Perl driver, it is available at Github. There is also documentation generated after every commit.

You can see if it's a good time to grab the bleeding edge code by seeing if the build is green.

To build the driver, run:

```
$ perl Makefile.PL
$ make
$ make test # make sure mongod is running, first
$ sudo make install
```

Please note that the tests will not pass without a mongod process running.

Note that the Perl driver requires some libraries available in CPAN. As of April, 2010, these are Any::Moose, Class::Method::Modifiers, Data::Types, DateTime, File::Slurp, Test::Exception, Try::Tiny, boolean, and Module::Install. (Additionally, Tie::IxHash is required for testing.) On Debian or Ubuntu systems, these prerequisites can be easily installed with the following command:

```
```

**Big-Endian Systems**

The driver will work on big-endian machines, but the database will not. The tests assume that mongod will be running on localhost unless %ENV{MONGOD} is set. So, to run the tests, start the database on a little-endian machine (at, say, "example.com") and then run the tests with:

```
MONGOD=example.com make test
```

A few tests that require a database server on "localhost" will be skipped.

**Next Steps**

There is a tutorial and API documentation on CPAN.

If you're interested in contributing to the Perl driver, check out Contributing to the Perl Driver.

**MongoDB Perl Tools**

**BSON**

BSON is a pure-Perl BSON implementation.

**Entities::Backend::MongoDB**

Entities::Backend::MongoDB is a backend for the Entities user management and authorization system stores all entities and relations between them in a MongoDB database, using the MongoDB module. This is a powerful, fast backend that gives you all the features of MongoDB.

**MojoX::Session::Store::MongoDB**

MojoX::Session::Store::MongoDB is a store for MojoX::Session that stores a session in a MongoDB database. Created by Ask Bjørn Hansen.

**MongoDB::Admin**

MongoDB::Admin is a collection of MongoDB administrative functions. Created by David Burley.

**Mongoose**
**Mongoose** is an attempt to bring together the full power of Moose with MongoDB. Created by Rodrigo de Oliveira Gonzalez.

**MongoDBI**

MongoDBI is an Object-Document-Mapper (ODM) for MongoDB. It allows you to create Moose-based classes to interact with MongoDB databases.

At-a-glance, most will enjoy MongoDBI for its ability to easily model classes while leveraging the power of MongoDB's schemaless and expeditious document-based design, dynamic queries, and atomic modifier operations.

Also noteworthy is MongoDBI's ease-of-use, chainable search facilities (filters), automated indexing, moose-integration (inheritance support, etc), lean document updates via dirty field tracking, and ability for each class to be configured to use a different database and connection, etc.

**MongoDBx-Class**

MongoDBx-Class is an ORM for MongoDB databases. MongoDBx::Class takes advantage of the fact that Perl's MongoDB driver is Moose-based to extend and tweak the driver's behavior, instead of wrapping it. This means MongoDBx::Class does not define its own syntax, so you simply use it exactly as you would the MongoDB driver directly. That said, MongoDBx::Class adds some sugar that enhances and simplifies the syntax unobtrusively (either use it or don't). Thus, it is relatively easy to convert your current MongoDB applications to MongoDBx::Class. A collection in MongoDBx::Class isa('MongoDB::Collection'), a database in MongoDBx::Class isa('MongoDB::Database'), etc. Created by Ido Perlmuter.

**MongoX**

MongoX - DSL sugar for MongoDB

**OOP Perl CMS**

OOP Perl CMS is based on Khurt Williams’ Object Oriented Perl methodology and can be used as a basic CMS framework or as a basis for your own CMS system. It uses Apache & mod_perl with MongoDB backend. Created by Waitman Gobble.

### Contributing to the Perl Driver

The easiest way to contribute is to file bugs and feature requests on Jira.

If you would like to help code the driver, read on...

**Finding Something to Help With**

**Fixing Bugs**

You can choose a bug on Jira and fix it. Make a comment that you're working on it, to avoid overlap.

**Writing Tests**

The driver could use a lot more tests. We would be grateful for any and all tests people would like to write.

**Adding Features**

If you think a feature is missing from the driver, you're probably right. Check on IRC or the mailing list, then go ahead and create a Jira case and add the feature. The Perl driver was a bit neglected for a while (although it's now getting a lot of TLC) so it's missing a lot of things that the other drivers have. You can look through their APIs for ideas.

**Contribution Guidelines**

The best way to make changes is to create an account on [Github], fork the driver, make your improvements, and submit a merge request.

To make sure your changes are approved and speed things along:

- Write tests. Lots of tests.
- Document your code.
- Write POD, when applicable.

Bonus (for C programmers, particularly):

- Make sure your change works on Perl 5.8, 5.10, Windows, Mac, Linux, etc.

**Code Layout**
Writing Drivers and Tools

Overview - Writing Drivers and Tools

This section contains information for developers that are working with the low-level protocols of Mongo - people who are writing drivers and higher-level tools.

Documents of particular interest:

<table>
<thead>
<tr>
<th>Document</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mongo Wire Protocol</td>
<td>Specification for the basic socket communications protocol used between Mongo and clients.</td>
</tr>
<tr>
<td>Mongo Driver Requirements</td>
<td>Description of what functionality is expected from a Mongo Driver</td>
</tr>
<tr>
<td>GridFS Specification</td>
<td>Specification of GridFS - a convention for storing large objects in Mongo</td>
</tr>
<tr>
<td>Mongo Extended JSON</td>
<td>Description of the extended JSON protocol for the REST-ful interface (ongoing development)</td>
</tr>
</tbody>
</table>

Additionally we recommend driver authors take a look at existing driver source code as an example.

- Back to driver development home page
- Drivers Home Page

Mongo Driver Requirements
This is a high-level list of features that a driver for MongoDB might provide. We attempt to group those features by priority. This list should be taken with a grain of salt, and probably used more for inspiration than as law that must be adhered to. A great way to learn about implementing a driver is by reading the source code of any of the existing drivers, especially the ones listed as “mongodb.org supported”.

High priority

- **BSON** serialization/deserialization
- full cursor support (e.g. support OP_GET_MORE operation)
- close exhausted cursors via OP_KILL_CURSORS
- support for running database commands
- handle query errors
- convert all strings to UTF-8 (part of proper support for BSON)
- hint, explain, count, $where
- database profiling: set/get profiling level, get profiling info
- advanced connection management (replica sets, slave okay)
- automatic reconnection

Medium priority

- validate a collection in a database
- buffer pooling
- Tailable cursor support

A driver should be able to connect to a single server. By default this must be localhost:27017, and must also allow the server to be specified by hostname and port.

```java
Mongo m = new Mongo(); // go to localhost, default port
Mongo m = new Mongo(String host, int port);
```

How the driver does this is up to the driver - make it idiomatic. However, a driver should make it explicit and clear what is going on.

Replica Sets

A driver must be able to support “Replica-Set” configurations, where more than one mongod servers are specified, and configured for hot-failover.

The driver should determine which of the nodes is the current master, and send all operations to that server. In the event of an error, either socket error or a “not a master” error, the driver must restart the determination process.

1. **Cluster Mode** Connect to master in master-slave cluster

```java
ServerCluster sc = new ServerCluster(INETAddr...); // again, give one and discover?
Mongo m = new Mongo(sc);
```

## Connect to slave in read-only mode in master-slave cluster

```java
ServerCluster sc = new ServerCluster(INETAddr...); // again, give one and discover?
sc.setTarget(...)
Mongo m = new Mongo(sc);
or maybe make it like *Default/Simple* w/ a flag?
```

Other than that, we need a way to get a DB object :

```java
Mongo m = new Mongo();
DB db = m.getDB(name);
```

And a list of db names (useful for tools…) :

```java
List<String> getDBNameList();
```

Database Object
Simple operations on a database object:

```java
/**
 * get name of database
 */
String dbName = db.getName();

/**
 * Get a list of all the collection names in this database
 */
List<String> cols = db.getCollectionNames();

/**
 * get a collection object. Can optionally create it if it
 * doesn't exist, or just be strict. (XJDM has strictness as an option)
 */
Collection coll = db.getCollection(string);

/**
 * Create a collection w/ optional options. Can fault
 * if the collection exists, or can just return it if it already does
 */
Collection coll = db.createCollection(string);
Collection coll = db.createCollection(string, options);

/**
 * Drop a collection by its name or by collection object.
 * Driver could invalidate any outstanding Collection objects
 * for that collection, or just hope for the best.
 */
boolean b = db.dropCollection(name);
boolean b = db.dropCollection(Collection);

/**
 * Execute a command on the database, returning the
 * BSON doc with the results
 */
Document d = db.executeCommand(command);

/**
 * Close the [logical] database
 */
void db.close();

/**
 * Erase / drop an entire database
 */
bool dropDatabase(dbname)
```

Database Administration

These methods have to do with database metadata: profiling levels and collection validation. Each admin object is associated with a database. These methods could either be built into the Database class or provided in a separate Admin class whose instances are only available from a database instance.
/* get an admin object from a database object. */
Admin admin = db.getAdmin();

/**
* Get profiling level. Returns one of the strings "off", "slowOnly", or
* "all". Note that the database returns an integer. This method could
* return an int or an enum instead --- in Ruby, for example, we return
* symbols.
*/
String profilingLevel = admin.getProfilingLevel();

/**
* Set profiling level. Takes whatever getProfilingLevel() returns.
*/
admin.setProfilingLevel("off");

/**
* Retrieves the database's profiling info.
*/
Document profilingInfo = admin.getProfilingInfo();

/**
* Returns true if collection is valid; raises an exception if not.
*/
boolean admin.validateCollection(collectionName);

Collection Basic Ops

/**
* full query capabilities - limit, skip, returned fields, sort, etc
*/
Cursor find(...);
void insert(...) // insert one or more objects into the collection, local variants on args
void remove(query) // remove objects that match the query
void update(selector, modifier) // modify all objects that match selector w/ modifier object
void updateFirst(selector, object) // replace first object that match selector w/ specified object
void upsert(selector, object) // replace first object that matches, or insert
long getCount();
long getCount(query);

Index Operations

void createIndex( index_info)
void dropIndex(name)
void dropIndexes()
List<info> getIndexInformation()

Misc Operations

document explain(query)
options getOptions();
string getName();
void close();

Cursor Object

document getNextDocument()
iterator getIterator() // again, local to language
bool hasMore()
void close()
Spec, Notes and Suggestions for Mongo Drivers

Assume that the BSON objects returned from the database may be up to 16MB. This size may change over time.

Feature Checklist for Mongo Drivers

Functionality Checklist

This section lists tasks the driver author might handle.

Essential

- BSON serialization/deserialization
- Basic operations: query, insert, update, remove, ensureIndex, findOne, limit, sort
- Fetch more data from a cursor when necessary (dbGetMore)
- Sending of KillCursors operation when use of a cursor has completed (ideally for efficiently these are sent in batches)
- Convert all strings to utf8
- Authentication

Recommended

- automatic _id generation
- Database $cmd support and helpers
- Detect { $err: ... } response from a db query and handle appropriately --see Error Handling in Mongo Drivers
- [Automatically connect to proper server, and failover], when connecting to a Replica Set ensureIndex commands should be cached to prevent excessive communication with the database. (Or, the driver user should be informed that ensureIndex is not a lightweight operation for the particular driver.)
- Support detecting max BSON size on connection (e.g., using buildinfo or isMaster commands) and allowing users to insert docs up to that size.

More Recommended

- lasterror helper functions
- count() helper function
- $where clause
- eval()
- File chunking (GridFS)
- hint fields
- explain helper

More Optional

- addUser, logout helpers
- Allow client user to specify Option_SlaveOk for a query
- Tailable cursor support
- In/out buffer pooling (if implementing in a garbage collected languages)

More Optional

- [connection pooling]
- Automatic reconnect on connection failure
- DBRef Support:
  - Ability to generate easily
  - Automatic traversal

Conventions for Mongo Drivers

Interface Conventions

It is desirable to keep driver interfaces consistent when possible. Of course, idioms vary by language, and when they do adaptation is appropriate. However, when the idiom is the same, keeping the interfaces consistent across drivers is desirable.

Terminology

In general, use these terms when naming identifiers. Adapt the names to the normal "punctuation" style of your language -- foo_bar in C might be fooBar in Java.

- database - what does this mean?
- collection
- index

Driver Testing Tools

Object IDs

- driverOIDTest for testing toString

```javascript
> db.runCommand({ "driverOIDTest" : new ObjectId() })
{
   "oid" : ObjectId("4b8991f221752a6e61a88267"),
   "str" : "4b8991f221752a6e61a88267",
   "ok" : 1
}
```

Mongo Wire Protocol

- Introduction
- Messages Types and Formats
  - Standard Message Header
  - Request Opcodes
- Client Request Messages
  - OP_UPDATE
  - OP_INSERT
  - OP_QUERY
  - OP_GETMORE
  - OP_DELETE
  - OP_KILL_CURSORS
  - OP_MSG
- Database Response Messages
  - OP_REPLY

Introduction

The Mongo Wire Protocol is a simple socket-based, request-response style protocol. Clients communicate with the database server through a regular TCP/IP socket.

- Default Socket Port
  - The default port is 27017, but this is configurable and will vary.

Clients should connect to the database with a regular TCP/IP socket. Currently, there is no connection handshake.
To describe the message structure, a C-like `struct` is used. The types used in this document (`cstring`, `int32`, etc.) are the same as those defined in the BSON specification. The standard message header is typed as `MsgHeader`. Integer constants are in capitals (e.g. `ZERO`).

In the case where more than one of something is possible (like in an `OP_INSERT` or `OP_KILL_CURSORS`), we again use the notation from the BSON specification (e.g. `int64*`). This simply indicates that one or more of the specified type can be written to the socket, one after another.

**Byte Ordering**

Note that like BSON documents, all data in the mongo wire protocol is little-endian.

**Messages Types and Formats**

There are two types of messages, client requests and database responses, each having a slightly different structure.

**Standard Message Header**

In general, each message consists of a standard message header followed by request-specific data. The standard message header is structured as follows:

```c
struct MsgHeader {
    int32   messageLength; // total message size, including this
    int32   requestID; // identifier for this message
    int32   responseTo; // requestID from original request
                      // (used in responses from db)
    int32   opCode; // request type - see table below

    /*
     * messageLength : This is the total size of the message in bytes. This total includes the 4 bytes that holds the message length.
     *
     * requestID : This is a client or database-generated identifier that uniquely identifies this message. For the case of client-generated messages
     *             (e.g. `OP_QUERY` and `CONTRIB:OP_GET_MORE`), it will be returned in the
     *             `responseTo` field of the `CONTRIB:OP_REPLY` message. Along with the `responseTo` field in responses, clients can use this to associate query
     *             responses with the originating query.
     *
     * responseTo : In the case of a message from the database, this will be the requestID taken from the `CONTRIB:OP_QUERY` or
     *              `CONTRIB:OP_GET_MORE` messages from the client. Along with the `requestID` field in queries, clients can use this to associate query
     *              responses with the originating query.
     *
     * opCode : Type of message. See the table below in the next section.
     */
}
```

Request Opcodes

The following are the currently supported opcodes:

<table>
<thead>
<tr>
<th>Opcode Name</th>
<th>OpCode value</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>OP_REPLY</td>
<td>1</td>
<td>Reply to a client request. responseTo is set</td>
</tr>
<tr>
<td>OP_MSG</td>
<td>1000</td>
<td>generic msg command followed by a string</td>
</tr>
<tr>
<td>OP_UPDATE</td>
<td>2001</td>
<td>update document</td>
</tr>
<tr>
<td>OP_INSERT</td>
<td>2002</td>
<td>insert new document</td>
</tr>
<tr>
<td>RESERVED</td>
<td>2003</td>

**Client Request Messages**

TableOfContents

Clients can send all messages except for CONTRIB:OP_REPLY. This is reserved for use by the database.

Note that only the CONTRIB:OP_QUERY and CONTRIB:OP_GET_MORE messages result in a response from the database. There will be no response sent for any other message.

You can determine if a message was successful with a getLastError command.

**OP_UPDATE**

The OP_UPDATE message is used to update a document in a collection. The format of a OP_UPDATE message is

```c
struct OP_UPDATE {
    MsgHeader header; // standard message header
    int32 ZERO; // 0 - reserved for future use
    cstring fullCollectionName; // *dbname.collectionname*
    int32 flags; // bit vector. see below
    document selector; // the query to select the document
    document update; // specification of the update to perform
}
```

**fullCollectionName**: The full collection name. The full collection name is the concatenation of the database name with the collection name, using a "." for the concatenation. For example, for the database "foo" and the collection "bar", the full collection name is "foo.bar".

**flags**:

<table>
<thead>
<tr>
<th>bit num</th>
<th>name</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Upsert</td>
<td>If set, the database will insert the supplied object into the collection if no matching document is found.</td>
</tr>
<tr>
<td>1</td>
<td>MultiUpdate</td>
<td>If set, the database will update all matching objects in the collection. Otherwise only updates first matching doc.</td>
</tr>
<tr>
<td>2-31</td>
<td>Reserved</td>
<td>Must be set to 0.</td>
</tr>
</tbody>
</table>

**selector**: BSON document that specifies the query for selection of the document to update.

**update**: BSON document that specifies the update to be performed. For information on specifying updates see the documentation on Updating.

There is no response to an OP_UPDATE message.

**OP_INSERT**

The OP_INSERT message is used to insert one or more documents into a collection. The format of the OP_INSERT message is

```c
struct {
    MsgHeader header; // standard message header
    int32 flags; // bit vector - see below
    cstring fullCollectionName; // *dbname.collectionname*
    document* documents; // one or more documents to insert into the collection
}
```

**fullCollectionName**: The full collection name. The full collection name is the concatenation of the database name with the collection name, using a "." for the concatenation. For example, for the database "foo" and the collection "bar", the full collection name is "foo.bar".

**documents**: One or more documents to insert into the collection. If there are more than one, they are written to the socket in sequence, one after another.

**flags**:

<table>
<thead>
<tr>
<th>bit num</th>
<th>name</th>
<th>description</th>
</tr>
</thead>
</table>

There is no response to an OP_INSERT message.

OP_QUERY

The OP_QUERY message is used to query the database for documents in a collection. The format of the OP_QUERY message is:

```c
struct OP_QUERY {
    MsgHeader header; // standard message header
    int32 flags; // bit vector of query options. See below for details.
    cstring fullCollectionName; // "dbname.collectionname"
    int32 numberToSkip; // number of documents to skip
    int32 numberToReturn; // number of documents to return
    // in the first OP_REPLY batch
    document query; // query object. See below for details.
    [ document returnFieldSelector; ] // Optional. Selector indicating the fields
    // to return. See below for details.
};
```

**flags:**

<table>
<thead>
<tr>
<th>bit num</th>
<th>name</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reserved</td>
<td>Must be set to 0.</td>
</tr>
<tr>
<td>1</td>
<td>TailableCursor</td>
<td>Tailable means cursor is not closed when the last data is retrieved. Rather, the cursor marks the final object's position. You can resume using the cursor later, from where it was located, if more data were received. Like any &quot;latent cursor&quot;, the cursor may become invalid at some point (CursorNotFound) – for example if the final object it references were deleted.</td>
</tr>
<tr>
<td>2</td>
<td>SlaveOk</td>
<td>Allow query of replica slave. Normally these return an error except for namespace &quot;local&quot;.</td>
</tr>
<tr>
<td>3</td>
<td>OplogReplay</td>
<td>Internal replication use only - driver should not set</td>
</tr>
<tr>
<td>4</td>
<td>NoCursorTimeout</td>
<td>The server normally times out idle cursors after an inactivity period (10 minutes) to prevent excess memory use. Set this option to prevent that.</td>
</tr>
<tr>
<td>5</td>
<td>AwaitData</td>
<td>Use with TailableCursor. If we are at the end of the data, block for a while rather than returning no data. After a timeout period, we do return as normal.</td>
</tr>
<tr>
<td>6</td>
<td>Exhaust</td>
<td>Stream the data down full blast in multiple &quot;more&quot; packages, on the assumption that the client will fully read all data queried. Faster when you are pulling a lot of data and know you want to pull it all down. Note: the client is not allowed to not read all the data unless it closes the connection.</td>
</tr>
<tr>
<td>7</td>
<td>Partial</td>
<td>Get partial results from a mongos if some shards are down (instead of throwing an error)</td>
</tr>
<tr>
<td>8-31</td>
<td>Reserved</td>
<td>Must be set to 0.</td>
</tr>
</tbody>
</table>

**fullCollectionName**: The full collection name. The full collection name is the concatenation of the database name with the collection name, using a "." for the concatenation. For example, for the database "foo" and the collection "bar", the full collection name is "foo.bar".

**numberToSkip**: Sets the number of documents to omit - starting from the first document in the resulting dataset - when returning the result of the query.

**numberToReturn**: Limits the number of documents in the first CONTRIB.OP_REPLY message to the query. However, the database will still establish a cursor and return the cursorID to the client if there are more results than numberToReturn. If the client driver offers 'limit' functionality (like the SQL LIMIT keyword), then it is up to the client driver to ensure that no more than the specified number of document are returned to the calling application. If numberToReturn is 0, the db will use the default return size. If the number is negative, then the database will return that number and close the cursor. No further results for that query can be fetched. If numberToReturn is 1 the server will treat it as -1 (closing the cursor automatically).

**query**: BSON document that represents the query. The query will contain one or more elements, all of which must match for a document to be included in the result set. Possible elements include $query, $orderby, $hint, $explain, and $snapshot.

**returnFieldSelector**: OPTIONAL BSON document that limits the fields in the returned documents. The returnFieldSelector contains one
or more elements, each of which is the name of a field that should be returned, and and the integer value 1. In JSON notation, a returnFieldsSelector to limit to the fields "a", "b" and "c" would be:

```
{ a : 1, b : 1, c : 1}
```

The database will respond to an OP_QUERY message with an CONTRIB:OP_REPLY message.

**OP_GETMORE**

The OP_GETMORE message is used to query the database for documents in a collection. The format of the OP_GETMORE message is:

```
struct {
    MsgHeader header; // standard message header
    int32     ZERO; // 0 - reserved for future use
    cstring   fullCollectionName; // "dbname.collectionname"
    int32     numberToReturn; // number of documents to return
    int64     cursorID; // cursorID from the OP_REPLY
}
```

- **fullCollectionName**: The full collection name. The full collection name is the concatenation of the database name with the collection name, using a "." for the concatenation. For example, for the database "foo" and the collection "bar", the full collection name is "foo.bar".

- **numberToReturn**: Limits the number of documents in the first CONTRIB:OP_REPLY message to the query. However, the database will still establish a cursor and return the cursorID to the client if there are more results than numberToReturn. If the client driver offers 'limit' functionality (like the SQL LIMIT keyword), then it is up to the client driver to ensure that no more than the specified number of document are returned to the calling application. If numberToReturn is 0, the db will used the default return size.

- **cursorID**: Cursor identifier that came in the CONTRIB:OP_REPLY. This must be the value that came from the database.

The database will respond to an OP_GETMORE message with a CONTRIB:OP_REPLY message.

**OP_DELETE**

The OP_DELETE message is used to remove one or more documents from a collection. The format of the OP_DELETE message is:

```
struct {
    MsgHeader header; // standard message header
    int32     ZERO; // 0 - reserved for future use
    cstring   fullCollectionName; // "dbname.collectionname"
    int32     flags; // bit vector - see below for details.
    document  selector; // query object. See below for details.
}
```

- **fullCollectionName**: The full collection name. The full collection name is the concatenation of the database name with the collection name, using a "." for the concatenation. For example, for the database "foo" and the collection "bar", the full collection name is "foo.bar".

- **flags**:

<table>
<thead>
<tr>
<th>bit num</th>
<th>name</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>SingleRemove</td>
<td>If set, the database will remove only the first matching document in the collection. Otherwise all matching documents will be removed.</td>
</tr>
<tr>
<td>1-31</td>
<td>Reserved</td>
<td>Must be set to 0.</td>
</tr>
</tbody>
</table>

- **selector**: BSON document that represent the query used to select the documents to be removed. The selector will contain one or more elements, all of which must match for a document to be removed from the collection. Please see $$$ TODO QUERY for more information.

There is no reponse to an OP_DELETE message.

**OP_KILL_CURSORS**

The OP_KILL_CURSORS message is used to close an active cursor in the database. This is necessary to ensure that database resources are reclaimed at the end of the query. The format of the OP_KILL_CURSORS message is:
struct {
    MsgHeader header; // standard message header
    int32     ZERO;   // 0 - reserved for future use
    int32     numberOfCursorIDs; // number of cursorIDs in message
    int64*    cursorIDs;        // sequence of cursorIDs to close
}

**numberOfCursorIDs**: The number of cursors that are in the message.

**cursorIDs**: "array" of cursor IDs to be closed. If there are more than one, they are written to the socket in sequence, one after another.

Note that if a cursor is read until exhausted (read until OP_QUERY or OP_GETMORE returns zero for the cursor id), there is no need to kill the cursor.

**OP_MSG**

Deprecated. OP_MSG sends a diagnostic message to the database. The database sends back a fixed response. The format is

```c
struct {
    MsgHeader header; // standard message header
cstring   message; // message for the database
}
```

Drivers do not need to implement OP_MSG.

**Database Response Messages**

**TableOfContents**

**OP_REPLY**

The OP_REPLY message is sent by the database in response to an OP_QUERY or OP_GET_MORE message. The format of an OP_REPLY message is:

```c
struct {
    MsgHeader header; // standard message header
    int32     responseFlags; // bit vector - see details below
    int64     cursorID;       // cursor id
    int32     startingFrom;  // where in the cursor this reply is starting
    int32     numberReturned; // number of documents in the reply
document* documents;      // documents
}
```

**responseFlags**:

<table>
<thead>
<tr>
<th>bit num</th>
<th>name</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>CursorNotFound</td>
<td>Set when getMore is called but the cursor id is not valid at the server. Returned with zero results.</td>
</tr>
<tr>
<td>1</td>
<td>QueryFailure</td>
<td>Set when query failed. Results consist of one document containing an &quot;$err&quot; field describing the failure.</td>
</tr>
<tr>
<td>2</td>
<td>ShardConfigStale</td>
<td>Drivers should ignore this. Only mongos will ever see this set, in which case, it needs to update config from the server.</td>
</tr>
<tr>
<td>3</td>
<td>AwaitCapable</td>
<td>Set when the server supports the AwaitData Query option. If it doesn't, a client should sleep a little between getMore's of a Tailable cursor. Mongod version 1.6 supports AwaitData and thus always sets AwaitCapable.</td>
</tr>
<tr>
<td>4-31</td>
<td>Reserved</td>
<td>Ignore</td>
</tr>
</tbody>
</table>

**cursorID**: The cursorID that this OP_REPLY is a part of. In the event that the result set of the query fits into one OP_REPLY message, `cursorID` will be 0. This cursorID must be used in any OP_GET_MORE messages used to get more data, and also must be closed by the client when no longer needed via a OP_KILL_CURSORS message.

**BSON**
BSON is a binary-encoded serialization of JSON-like documents. BSON is designed to be lightweight, traversable, and efficient. BSON, like JSON, supports the embedding of objects and arrays within other objects and arrays. See `bsonspec.org` for the spec and more information in general.

**BSON and MongoDB**

MongoDB uses BSON as the data storage and network transfer format for "documents".

BSON at first seems BLOB-like, but there exists an important difference: theMongo database understands BSON internals. This means that MongoDB can "reach inside" BSON objects, even nested ones. Among other things, this allows MongoDB to build indexes and match objects against query expressions on both top-level and nested BSON keys.

See also: the BSON blog post and BSON and Data Interchange

**Language-Specific Examples**

We often map from a language's "dictionary" type – which may be its native objects – to BSON. The mapping is particularly natural in dynamically typed languages:

```javascript
JavaScript: {'foo': 'bar'}
```

```perl
Perl: {'foo' => 'bar'}
```

```php
PHP: array('foo' => 'bar')
```

```ruby
Ruby: {'foo' => 'bar'}
```

```java
Java: DBObject obj = new BasicDBObject("foo", "bar");
```

```c
C
bson b;
bson_buffer buf;
bson_buffer_init( &buf )
bson_append_string( &buf, "name", "Joe" );
bson_append_int( &buf, "age", 33 );
bson_from_buffer( &b, &buf );
bson_print( &b );
```

```cpp
C++
BSONObj p = BSON( "name" << "Joe" << "age" << 33 );
cout << p.toString() << endl;
cout << p["age"].number() << endl;
```

```java
Java
```

See the BSON section of the C++ Tutorial for more information.
BasicDBObject doc = new BasicDBObject();
doc.put("name", "MongoDB");
doc.put("type", "database");
doc.put("count", 1);
BasicDBObject info = new BasicDBObject();
info.put("x", 203);
info.put("y", 102);
doc.put("info", info);
coll.insert(doc);

**PHP**

The PHP driver includes `bson_encode` and `bson_decode` functions. `bson_encode` takes any PHP type and serializes it, returning a string of bytes:

```php
$bson = bson_encode(null);
bson = bson_encode(true);
bson = bson_encode(4);
bson = bson_encode("hello, world");
bson = bson_encode(array("foo" => "bar"));
bson = bson_encode(new MongoDate());
```

Mongo-specific objects (MongoId, MongoDate, MongoRegex, MongoCode) will be encoded in their respective BSON formats. For other objects, it will create a BSON representation with the key/value pairs you would get by running for ($object as $key => $value).

`bson_decode` takes a string representing a BSON object and parses it into an associative array.

**Python**

```python
>>> from bson import BSON
>>> bson_string = BSON.encode({"hello": "world"})
>>> bson_string
'\x16\x00\x00\x00\x02hello\x00\x06\x00\x00\x00world\x00\x00'
>>> bson_string.decode()
{u'hello': u'world'}
```

PyMongo also supports "ordered dictionaries" through the `bson.son` module. The `BSON` class can handle `SON` instances using the same methods you would use for regular dictionaries. Python2.7's collections.OrderedDict is also supported.

**Ruby**

There are now two gems that handle BSON-encoding: bson and bson_ext. These gems can be used to work with BSON independently of the MongoDB Ruby driver.

```ruby
irb
>> require 'rubygems'
=> true
>> require 'bson'
=> true
>> doc = {:hello => "world"}
>> bson = BSON.serialize(doc).to_s
=> "\x02\x00\x00\x00\x00\x02hello\x00\x06\x00\x00\x00world\x00\x00"
>> BSON.deserialize(bson.unpack("C"))
=> {"hello" => "world"}
```

The BSON class also supports ordered hashes. Simply construct your documents using the OrderedHash class, also found in the MongoDB Ruby Driver.

**MongoDB Document Types**

MongoDB uses BSON documents for three things:

1. Data storage (user documents). These are the regular JSON-like objects that the database stores for us. These BSON documents are
sent to the database via the INSERT operation. User documents have limitations on the "element name" space due to the usage of special characters in the JSON-like query language.

a. A user document element name cannot begin with "$".
b. A user document element name cannot have a "." in the name.
c. The element name "_id" is reserved for use as a primary key id, but you can store anything that is unique in that field.

The database expects that drivers will prevent users from creating documents that violate these constraints.

2. Query "Selector" Documents: Query documents (or selectors) are BSON documents that are used in QUERY, DELETE and UPDATE operations. They are used by these operations to match against documents. Selector objects have no limitations on the "element name" space, as they must be able to supply special "marker" elements, like "$where" and the special "command" operations.

3. "Modifier" Documents: Documents that contain 'modifier actions' that modify user documents in the case of an update (see Updating).

**Mongo Extended JSON**

MongoDB's import and export utilities, as well as its basic REST interface, support JSON-style access to MongoDB BSON documents. Special representations are used for BSON types that do not have obvious JSON mappings, and multiple representations are allowed for some such types. The REST interface supports three different modes for document output { Strict, JS, Shell }, which serve to control the representations used. MongoDB can understand all of these representations in REST input.

- **Strict** mode produces output conforming to the JSON RFC spec [http://www.json.org](http://www.json.org).
- **JS** mode produces output that can be processed by most Javascript interpreters.
- **Shell / "TenGen"** mode produces output that the mongo shell understands. This is basically an enhanced Javascript format.

The following BSON types are represented using special conventions:

<table>
<thead>
<tr>
<th>BSON Data Type</th>
<th>Strict</th>
<th>JS</th>
<th>Mongo Shell (&quot;TenGen&quot;)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_binary</td>
<td>{ &quot;$binary&quot; :&lt;bindata&gt;, &quot;$type&quot;: &quot;&lt;t&gt;&quot; }</td>
<td>{ &quot;$binary&quot; :&lt;bindata&gt;, &quot;$type&quot;: &quot;&lt;t&gt;&quot; }</td>
<td>{ &quot;$binary&quot; :&lt;bindata&gt;, &quot;$type&quot;: &quot;&lt;t&gt;&quot; }</td>
<td>&lt;bindata&gt; base64 represents a binary string, &lt;t&gt; hexadecimal represents a single indicating a data type.</td>
</tr>
<tr>
<td>data_date</td>
<td>{ &quot;$date&quot; :&lt;date&gt; }</td>
<td>Date( &lt;date&gt; )</td>
<td>Date(&lt;date&gt;)</td>
<td>&lt;date&gt; is a JSON representation of a 64 bit signed integer for milliseconds since epoch (unsigned before version 1.9.1).</td>
</tr>
<tr>
<td>data_timestamp</td>
<td>{ &quot;$timestamp&quot; :&lt;t&gt;, &quot;$i&quot;: &lt;i&gt; }</td>
<td>{ &quot;$timestamp&quot; :&lt;t&gt;, &quot;$i&quot;: &lt;i&gt; }</td>
<td>Timestamp(&lt;t&gt;,&lt;i&gt;)</td>
<td>&lt;t&gt; is the represents a 32 bit unsigned integer for seconds since epoch, &lt;i&gt; 32 bit unsigned integer for increment.</td>
</tr>
</tbody>
</table>
### GridFS Specification

- **Introduction**
- **Specification**
  - **Storage Collections**
Introduction

GridFS is a storage specification for large objects in MongoDB. It works by splitting large object into small chunks, usually 256k in size. Each chunk is stored as a separate document in a `chunks` collection. Metadata about the file, including the filename, content type, and any optional information needed by the developer, is stored as a document in a `files` collection.

So for any given file stored using GridFS, there will exist one document in `files` collection and one or more documents in the `chunks` collection.

If you're just interested in using GridFS, see the docs on storing files. If you'd like to understand the GridFS implementation, read on.

Specification

Storage Collections

GridFS uses two collections to store data:

- `files` contains the object metadata
- `chunks` contains the binary chunks with some additional accounting information

In order to make more than one GridFS namespace possible for a single database, the files and chunks collections are named with a prefix. By default the prefix is `fs`, so any default GridFS store will consist of collections named `fs.files` and `fs.chunks`. The drivers make it possible to change this prefix, so you might, for instance, have another GridFS namespace specifically for photos where the collections would be `photos.files` and `photos.chunks`.

Here's an example of the standard GridFS interface in Java:

```java
/*
 * default root collection usage - must be supported
 */
GridFS myFS = new GridFS(myDatabase); // returns a default GridFS (e.g. "fs" root collection)
myFS.storeFile(new File("/tmp/largething.mpg")); // saves the file into the "fs" GridFS store

/*
 * specified root collection usage - optional
 */
GridFS myContracts = new GridFS(myDatabase, "contracts"); // returns a GridFS where "contracts" is root
myFS.retrieveFile("smithco", new File("/tmp/smithco_20090105.pdf")); // retrieves object whose filename is "smithco"
```

Note that the above API is for demonstration purposes only - this spec does not (at this time) recommend any API. See individual driver documentation for API specifics.

documents

Documents in the `files` collection require the following fields:

```
{
   "_id" : <unspecified>,   // unique ID for this file
   "length" : data_number,   // size of the file in bytes
   "chunkSize" : data_number,   // size of each of the chunks. Default is 256k
   "uploadDate" : data_date,   // date when object first stored
   "md5" : data_string        // result of running the "filemd5" command on this file's
chunks
}
```

Any other desired fields may be added to the files document; common ones include the following:
Note that the `_id` field can be of any type, per the discretion of the spec implementor.

The structure of documents from the `chunks` collection is as follows:

```json
{
   "_id": <unspecified>, // object id of the chunk in the _chunks collection
   "files_id": <unspecified>, // _id of the corresponding files collection entry
   "n": chunk_number, // chunks are numbered in order, starting with 0
   "data": data_binary, // the chunk's payload as a BSON binary type
}
```

Notes:
- The `_id` is whatever type you choose. As with any MongoDB document, the default will be a BSON object id.
- The `files_id` is a foreign key containing the `_id` field for the relevant `files` collection entry

**Indexes**

GridFS implementations should create a unique, compound index in the `chunks` collection for `files_id` and `n`. Here's how you'd do that from the shell:

```sql
db.fs.chunks.ensureIndex({files_id:1, n:1}, {unique: true});
```

This way, a chunk can be retrieved efficiently using its `files_id` and `n` values:

```sql
cursor = db.fs.chunks.findOne({files_id: myFileID}).sort({n:1});
```

**Implementing Authentication in a Driver**

The current version of Mongo supports only very basic authentication. One authenticates a username and password in the context of a particular database. Once authenticated, the user has full read and write access to the database in question.

The `admin` database is special. In addition to several commands that are administrative being possible only on `admin`, authentication on `admin` gives one read and write access to all databases on the server. Effectively, `admin` access means root access to the `db`.

Note on a single socket we may authenticate for any number of databases, and as different users. This authentication persists for the life of the database connection (barring a `logout` command).

**The Authentication Process**

Authentication is a two step process. First the driver runs a `getnonce` command to get a nonce for use in the subsequent authentication. We can view a sample `getnonce` invocation from `dbshell`:

```sql
> db.$cmd.findOne({getnonce:1})
{ "nonce":"7268c504683936e1", "ok":1
```

The nonce returned is a hex String.

The next step is to run an `authenticate` command for the database on which to authenticate. The `authenticate` command has the form:
where

- `username` is a username in the database’s `system.users` collection;
- `nonce` is the nonce returned from a previous `getnonce` command;
- `digest` is the hex encoding of a MD5 message digest which is the MD5 hash of the concatenation of `(nonce, username, password_digest)`, where `password_digest` is the user’s password value in the `pwd` field of the associated user object in the database’s `system.users` collection. `pwd` is the hex encoding of `username + "mongo:" + password_text`.

Authenticate will return an object containing

```
{ ok : 1 }
```

when successful.

Details of why an authentication command failed may be found in the Mongo server’s log files.

The following code from the Mongo Javascript driver provides an example implementation:

```javascript
DB.prototype.addUser = function( username , pass ){  
    var c = this.getCollection( "system.users" );

    var u = c.findOne( { user : username } ) || { user : username };
    u.pwd = hex_md5( username + pass );
    print( tojson( u ) );
    c.save( u );
}

DB.prototype.auth = function( username , pass ){  
    var n = this.runCommand( { getnonce : 1 } );

    var a = this.runCommand(  
        {  
            authenticate : 1 ,
            user : username ,
            nonce : n.nonce ,
            key : hex_md5( n.nonce + username + hex_md5( username + "mongo:" + pass ) )
        }  
    );
    return a.ok;
}
```

Logout

Drivers may optionally implement the logout command which deauthorizes usage for the specified database for this connection. Note other databases may still be authorized.

Alternatively, close the socket to deauthorize.

```javascript
> db.$cmd.findOne({logout:1})
{  
    "ok" : 1.0  
}
```

Replica Sets and Authentication

For drivers that support replica sets, extra care with replication is required.

When switching from one server in a replica set to another, for example in a failover situation, you must reauthenticate. Clients will likely want to cache authentication from the user so that the client can reauthenticate with the new server when appropriate.
Be careful also with operations such as Logout. If you log out from only some members of a replica set, that could be an issue.

Authenticating with a server in slave mode is allowed.

**See Also**

- Security and Authentication

**Notes on Pooling for Mongo Drivers**

Note that with the `db` write operations can be sent asynchronously or synchronously (the latter indicating a `getlasterror` request after the write).

When asynchronous, one must be careful to continue using the same connection (socket). This ensures that the next operation will not begin until after the write completes.

**Pooling and Authentication**

An individual socket connection to the database has associated authentication state. Thus, if you pool connections, you probably want a separate pool for each authentication case (db + username).

**Pseudo-code**

The following pseudo-code illustrates our recommended approach to implementing connection pooling in a driver's connection class. This handles authentication, grouping operations from a single "request" onto the same socket, and a couple of other gotchas:

```python
class Connection:
    def __init__(self, pool_size, addresses, auto_start_requests):
        self.pool_size = pool_size
        self.addresses = addresses
        self.auto_start_requests = auto_start_requests
        self.thread_map = {}
        self.locks = Lock[pool_size]
        selfsockets = Socket[pool_size]
        self.socket_auth = String[pool_size][]
        self.auth = {}

    def find_master(self):
        for address in self.addresses:
            if address.is_master():
                self.master = address

    def pick_and_acquire_socket(self):
        choices = random permutation of [0, ..., self.pool_size - 1]
        choices.sort(order: ascending, value: size of preimage of choice under self.thread_map)

        for choice in choices:
            if self.locks[choice].non_blocking_acquire():
                return choice

        sock = choices[0]
        self.locks[sock].blocking_acquire()
        return sock

    def get_socket(self):
        sock_number = self.thread_map[current_thread] >= 0:
            sock_number = self.thread_map[current_thread]
            self.locks[sock_number].blocking_acquire()
        else:
            sock_number = self.pick_and_lock_socket()
            if self.auto_start_requests or current_thread in self.thread_map:
                self.thread_map[current_thread] = sock_number
```

if not this.socket[sock_number]:
    this.socket[sock_number] = Socket(this.master)

return sock_number

send_message_without_response(message):
    sock_number = this.get_socket()
    this.check_auth()
    this.socket[sock_number].send(message)
    this.locks[sock_number].release()

send_message_with_response(message):
    sock_number = this.get_socket()
    this.check_auth()
    this.socket[sock_number].send(message)
    result = this.socket[sock_number].receive()
    this.locks[sock_number].release()
    return result

# start_request is only needed if auto_start_requests is False
start_request():
    this.thread_map[current_thread] = -1

end_request():
    delete this.thread_map[current_thread]

authenticate(database, username, password):
    # TODO should probably make sure that these credentials are valid,
    # otherwise errors are going to be delayed until first op.
    this.auth[database] = (username, password)

logout(database):
    delete this.auth[database]

check_auth(sock_number):
    for db in this.socket_auth[sock_number]:
        if db not in this.auth.keys():
            this.socket[sock_number].send(logout_message)
            this.socket_auth[sock_number].remove(db)
    for db in this.auth.keys():
        if db not in this.socket_auth[sock_number]:
            this.socket[sock_number].send(authenticate_message)
            this.socket_auth[sock_number].append(db)

# somewhere we need to do error checking - if you get not master then everything
# in this.socket gets closed and set to null and we call find_master() again.
Connecting Drivers to Replica Sets

Ideally a MongoDB driver can connect to a cluster of servers which represent a replica set, and automatically find the right set member with which to communicate. Failover should be automatic too. The general steps are:

1. The user, when opening the connection, specifies host[:port] for one or more members of the set. Not all members need be specified -- in fact the exact members of the set might change over time. This list for the connect call is the seed list.
2. The driver then connects to all servers on the seed list, perhaps in parallel to minimize connect time. Send an ismaster command to each server.
3. When the server is in replSet mode, it will return a hosts field with all members of the set that are potentially eligible to serve data. The client should cache this information. Ideally this refreshes too, as the set's config could change over time.
4. Choose a server with which to communicate.
   a. If ismaster == true, that server is primary for the set. This server can be used for writes and immediately consistent reads.
   b. If secondary == true, that server is not primary, but is available for eventually consistent reads. In this case, you can use the primary field to see which server the master should be. (If primary is not set, you may want to poll other nodes at random; it is conceivable that the member to which we are talking is partitioned from the other members, and thus it cannot determine who is primary on its own. This is unlikely but possible.)
5. If an error occurs with the current connection, find the new primary and resume use there.

For example, if we run the ismaster command on a non-primary server, we might get something like:

```javascript
> db.runCommand("ismaster")
{
   "ismaster" : false,
   "secondary" : true,
   "hosts" : [
      "ny1.acme.com",
      "ny2.acme.com",
      "sf1.acme.com"
   ],
   "passives" : [
      "ny3.acme.com",
      "sf3.acme.com"
   ],
   "arbiters" : [
      "sf2.acme.com",
   ]
   "primary" : "ny2.acme.com",
   "ok" : true
}
```

There are three servers with priority > 0 (ny1, ny2, and sf1), two passive servers (ny3 and sf3), and an arbiter (sf2). The primary should be ny2, but the driver should call ismaster on that server before it assumes it is.

Error Handling in Mongo Drivers

If an error occurs on a query (or getMore operation), Mongo returns an error object instead of user data.

The error object has a first field guaranteed to have the reserved key $err. For example:

```javascript
{ $err : "some error message" }
```

The $err value can be of any type but is usually a string.

Drivers typically check for this return code explicitly and take action rather than returning the object to the user. The query results flags include a
set bit when $err is returned.

```c
/* db response format

Query or GetMore: // see struct QueryResult
int resultFlags;
int64 cursorID;
int startingFrom;
int nReturned;
list of marshalled JSObjects;
*/

struct QueryResult : public MsgData {
enum {
    ResultFlag_CursorNotFound = 1, /* returned, with zero results, when getMore is called but the
cursor id is not valid at the server. */
    ResultFlag_ErrSet = 2          /* { $err : ... } is being returned */
};
...}
```

**Introduction**

MongoDB is a collection-oriented, schema-free document database.

By *collection-oriented*, we mean that data is grouped into sets that are called 'collections'. Each collection has a unique name in the database, and can contain an unlimited number of documents. Collections are analogous to tables in a RDBMS, except that they don't have any defined schema.

By *schema-free*, we mean that the database doesn't need to know anything about the structure of the documents that you store in a collection. In fact, you can store documents with different structure in the same collection if you so choose.

By *document*, we mean that we store data that is a structured collection of key-value pairs, where keys are strings, and values are any of a rich set of data types, including arrays and documents. We call this data format "**BSON**" for "Binary Serialized dOcument Notation."

**MongoDB Operational Overview**

MongoDB is a server process that runs on Linux, Windows and OS X. It can be run both as a 32 or 64-bit application. We recommend running in 64-bit mode, since Mongo is limited to a total data size of about 2GB for all databases in 32-bit mode.

The MongoDB process listens on port 27017 by default (note that this can be set at start time - please see [Command Line Parameters](#) for more information).

Clients connect to the MongoDB process, optionally authenticate themselves if security is turned on, and perform a sequence of actions, such as inserts, queries and updates.

MongoDB stores its data in files (default location is `/data/db/`), and uses memory mapped files for data management for efficiency.

MongoDB can also be configured for automatic data replication, as well as automatic fail-over.
MongoDB Functionality

As a developer, MongoDB drivers offer a rich range of operations:

- Queries: Search for documents based on either query objects or SQL-like "where predicates". Queries can be sorted, have limited return sizes, can skip parts of the return document set, and can also return partial documents.
- Inserts and Updates: Insert new documents, update existing documents.
- Index Management: Create indexes on one or more keys in a document, including substructure, deleted indexes, etc.
- General commands: Any MongoDB operation can be managed via DB Commands over the regular socket.

**mongod process "disappeared"

Scenario here is the log ending suddenly with no error or shutdown messages logged.

On Unix, check /var/log/messages:

```
$ sudo grep mongod /var/log/messages
$ sudo grep score /var/log/messages
```

Socket errors in sharded clusters and replica sets

If you're experiencing unexplainable socket errors between nodes in a sharded cluster or replica set, you may want to check your TCP keepalive time. The default Linux keepalive time is 7200 seconds (2 hours); we recommend that you change this to 300 seconds (five minutes).

To check your current setting:

```bash
$ sudo sysctl net.ipv4.tcp_keepalive_time
```
You'll usually see this:

```
7200
```

To change this setting:

```
echo 300 > /proc/sys/net/ipv4/tcp_keepalive_time
```

Note that you must alter the `tcp_keepalive_time` value on all machines hosting MongoDB processes. This include machines hosting `mongos` routers, config servers, and `mongod` servers. You should not need to restart the mongo processes themselves, the setting will take effect immediately.

**Excessive Disk Space**

- Understanding Disk Usage
  - `local.*` files and replication
  - Datafile Preallocation
  - Recovering Deleted Space
  - Running out of disk space
  - Checking Size of a Collection
  - Helpful scripts

**Understanding Disk Usage**

You may notice that for a given set of data the MongoDB datafiles in `/data/db` are larger than the data set inserted into the database. There are several reasons for this.

**local.* files and replication**

The replication oplog is preallocated as a capped collection in the local database.

The default allocation is approximately 5% of disk space (64 bit installations).

If you would like a smaller oplog size use the `--oplogSize` command line parameter.

**Datafile Preallocation**

Each datafile is preallocated to a particular size. (This is done to prevent file system fragmentation, among other reasons.) The first filename for a database is `<dbname>.0`, then `<dbname>.1`, etc. `<dbname>.0` will be 64MB, `<dbname>.1` 128MB, etc, up to 2GB. Once the files reach 2GB in size, each successive file is also 2GB.

Thus, if the last datafile present is, say, 1GB, that file might be 90% empty if it was recently created.

Additionally, on Unix, mongod will preallocate an additional datafile in the background and do background initialization of this file. These files are prefilled with zero bytes. This initialization can take up to a minute (less on a fast disk subsystem) for larger datafiles. Pre-filling in the background prevents significant delays when a new database file is next allocated.

On Windows prior to v2.1.2, additional datafiles are not preallocated. NTFS can allocate large files filled with zeroes relatively quickly, rendering preallocation unnecessary.

As soon as a datafile starts to be used, the next one will be preallocated.

You can disable preallocation with the `--noprealloc` command line parameter. This flag is nice for tests with small datasets where you drop the database after each test. It should not be used on production servers.

For large databases (hundreds of GB or more), this is of no significant consequence as the unallocated space is relatively small.
On Linux systems you can use `hdparm` to allocate files to get an idea of how costly allocation might be:

```
time hdparm --fallocate $((1024*1024)) testfile
```

**Recovering Deleted Space**

MongoDB maintains lists of deleted blocks within the datafiles when objects or collections are deleted. This space is reused by MongoDB but never freed to the operating system.

To shrink the amount of physical space used by the datafiles themselves, by reclaiming deleted blocks, you must rebuild the database by using (`db.repairDatabase()`).

> repairDatabase copies all the database records to new file(s). You will need enough free disk space to hold both the old and new database files while the repair is running. Be aware that repairDatabase will block and will take a long time to complete.

Rather than compacting an entire database, you can compact just a single collection by using `db.runCommand({compact:'collectionname'})`. This does not shrink any datafiles, however; it only defragments deleted space so that larger objects might reuse it. The compact command will never delete or shrink database files, and in general requires extra space to do its work. Thus, it is not a good option when you are running critically low on disk space.

> When testing and investigating the size of datafiles, if your data is just test data, use `db.dropDatabase()` to clear all datafiles and start fresh.

**Running out of disk space**

If your server runs out of disk space for data files you will see something like this in the log:

```
Thu Aug 11 13:06:09 [FileAllocator] allocating new datafile dbms/test.13, filling with zeroes...
Thu Aug 11 13:06:19 [FileAllocator] allocating new datafile dbms/test.13, filling with zeroes...
Thu Aug 11 13:06:19 [FileAllocator] will try again in 10 seconds
```

The server remains in this state forever blocking all writes including deletes. However, reads still work. To delete some data and compact (see above), you must restart the server first.

If your server runs out of disk space for journal files, the server process will abort (exit). By default, journal files are created in a subdirectory called "journal" in the data directory, but you may elect to put the journal files on another disk by using a symlink.

**Checking Size of a Collection**

Use the `validate` command to check the size of a collection -- that is from the shell run:

```
> db.<collectionname>.validate();

> // these are faster:
> db.<collectionname>.dataSize(); // just data size for collection
> db.<collectionname>.storageSize(); // allocation size including unused space
> db.<collectionname>.totalSize(); // data + index
> db.<collectionname>.totalIndexSize(); // index data size
```

This command returns info on the collection data but note there is also data allocated for associated indexes. These can be checked with validate too, if one looks up the index's namespace name in the system.namespaces collection. For example:
Helpful scripts

These one-line scripts will print the stats for each db/collection:

```javascript
db._adminCommand("listDatabases").databases.forEach(function (d) {mdb = db.getSiblingDB(d.name); printjson(mdb.stats())})
db._adminCommand("listDatabases").databases.forEach(function (d) {mdb = db.getSiblingDB(d.name); mdb.getCollectionNames().forEach(function(c) {s = mdb[c].stats(); printjson(s)}))
```

Starting and Stopping Mongo

- **Starting mongod**
  - Starting with Default Data Directory and TCP Port
  - Specifying a Data Directory
  - Specifying a TCP Port
  - Running as a Daemon
- **Stopping mongod**
  - Control-C
  - Sending shutdownServer() message from the mongo shell
  - Sending a Unix INT or TERM signal
- **Memory Usage**

MongoDB is run as a standard program from the command line. Please see Command Line Parameters for more information on those options. For information about running mongod or mongos as a service in Windows, see Windows Service.

The following examples assume that you are in the directory where the mongod executable resides. mongod is the primary database process that runs on an individual server. mongos is the sharding process. mongo is the administrative shell. This page discusses mongod.

**Starting mongod**

- **Starting with Default Data Directory and TCP Port**

To start Mongo in default mode, where data will be stored in the /data/db directory (or c:\data\db on Windows), and listening on port 27017, just type

```bash
$ ./mongod
```
**Specifying a Data Directory**

To specify a directory forMongo to store files, use the `--dbpath` option:

```
$ ./mongod --dbpath /var/lib/mongodb/
```

Note that you must create the directory and set its permissions appropriately ahead of time -- Mongo will not create the directory if it doesn't exist.

**Specifying a TCP Port**

You can specify a different port for Mongo to listen on for connections from clients using the `--port` option.

```
$ ./mongod --port 12345
```

Use this when running several mongod processes on a single machine. *It is highly recommended to use the default port number whenever possible to avoid any confusion.*

Note: if you use the `--configsvr` or `--shardsvr` command line options, those parameters will select an appropriate port number automatically (more info). Port 27017 is by convention the port to which client applications talk to the cluster. Thus if you are unsharded, mongod would be listening on 27017, but if sharded, the mongos process would be.

**Running as a Daemon**

Note: these options are only available in MongoDB version 1.1 and later.

This will fork the Mongo server and redirect its output to a logfile. As with `--dbpath`, you must create the log path yourself, Mongo will not create parent directories for you.

```
$ ./mongod --fork --logpath /var/log/mongodb.log --logappend
```

**Stopping mongod**

**Control-C**

If you have Mongo running in the foreground in a terminal, you can simply "Ctrl-C" the process. This will cause Mongo to do a clean exit, flushing and closing its data files. Note that it will wait until all ongoing operations are complete.

**Sending shutdownServer() message from the mongo shell**

The shell can request that the server terminate.

```
$ ./mongo
> use admin
> db.shutdownServer()
```

This command only works from localhost or if one is authenticated.

From a driver (where the helper function may not exist), one can run the command

```
{ "shutdown" : 1 }
```

If this server is the primary in a replica set, it will go through the following process (version 1.9.1+):

1. Check how up-to-date the secondaries are.
2. If no secondary within 10 seconds of the primary, return that we won't shut down (optionally pass the `timeoutSecs` option to wait for a secondary to catch up.
3. If there is a secondary within 10 seconds of the primary, the primary will step down and wait for the secondary to catch up.
4. After 60 seconds or once the secondary has caught up, the primary will shut down.

If there is no up-to-date secondary and you want the primary to shut down anyway, you can use `force : true:`
You can also specify `timeoutSecs : N`, which will keep checking the secondaries for N seconds if none are immediately up-to-date. If any of the secondaries catch up within N seconds, the primary will shut down. If no secondaries catch up, it will not shut down.

```
> db.adminCommand({shutdown : 1, timeoutSecs : 5})
> // or
> db.shutdownServer({timeoutSecs : 5})
```

**Sending a Unix INT or TERM signal**

You can cleanly stop `mongod` using a SIGINT or SIGTERM signal on Unix-like systems. Either ^C, "kill -2 PID," or `kill -15 PID` will work.

Sending a KILL signal `kill -9` will probably cause damage if `mongod` is not running with `Journaling`. (Journaling is on by default for 64 bit `mongod`.) See also: `repairDatabase command`.

After a hard crash, when not using `--journal`, MongoDB will say it was not shutdown cleanly, and ask you to do a repair of the database.

**Memory Usage**

Mongo uses memory mapped files to access data, which results in large numbers being displayed in tools like top for the `mongod` process. This is not a concern, and is normal when using memory-mapped files. Basically, the size of mapped data is shown in the virtual size parameter, and resident bytes shows how much data is being cached in RAM.

You can get a feel for the "inherent" memory footprint of Mongo by starting it fresh, with no connections, with an empty /data/db directory and looking at the resident bytes.

**Tag Aware Sharding**

In 2.2, MongoDB adds additional support for custom partitioning in sharded clusters – specifically sharded collections. By using this "tag aware" sharding and balancing, you can (automatically) ensure that data in a sharded database system is always on specific shards. This can be used to ensure data is geographically close to the systems which use it. You can also restrict sharded collections to only a few shards, therefore federating a set of shards for different uses.

Shard tagging controls data location, and is complementary but separate from replica set tagging – which can be used to enforce writing (and reading with Read Preferences within the replica set) within the replica set.

For example you can tag all "USA" data (by defining a range of your shard key which contains the "USA" data) to one or more shards (by tagging those shards with "USA").

Typically this is used to make assignment of documents to shards geographically aware. One marks a shard key range as "homed" on a certain set of shards. Those shards would then be configured such that their primary defaults to the desired data center / geography.
Data Center Awareness

- **Examples**
  - One primary data center, one disaster recovery site
  - Multi-site with local reads
  - Confirming propagation of writes with getLastError
  - Replicating from nearby members
  - Tagging (version 2.0+)
    - Server $X$ should have a copy.
    - Make $n$ backups
    - Make sure there are at least three copies of the data and it is present on at least two continents.
    - Make sure at least two servers across at least two racks in nyc have it.
- **Notes**
- **See Also**

### Examples

**One primary data center, one disaster recovery site**

In this example set members at the main data center (sf) are eligible to become primary. In addition we have a member at a remote site that is never primary (at least, not without human intervention).
Multi-site with local reads

The following example shows one set member in each of three data centers. At election time, any healthy up-to-date node, arbitrarily, can become primary. The others are then secondaries and can service queries locally if the client uses slaveOk read preference modes.

Refer to your driver's documentation for more information about read routing.

Confirming propagation of writes with getLastError

Calling getLastError (called "write concern" in some drivers) with w:"majority" (v2.0+) assures the write reaches a majority of the set before acknowledgement. For example, if you had a three-member replica set, calling `db.runCommand({getLastError : 1, w : "majority"})` would make sure the last write was propagated to at least 2 servers.

Once a write reaches a majority of the set members, the cluster wide commit has occurred (see Replica Set Design Concepts).

Replicating from nearby members

In v2.0+, secondaries automatically sync data from members which are nearby. You can see the latencies that the `mongod` process is observing to its peers in the `replSetGetStatus` command's output. If nearby members are not healthy, more distant members will be used for syncing.

Example output, highlighting new ping time and sync target fields:

```
> rs.status()
{...
  "syncingTo" : "B:27017",
  "members" : [
    { "_id" : 0,
      "name" : "A:27017",
      ...
      "self" : true
    },
    { "_id" : 1,
      "name" : "B:27017",
      ...
      "pingMs" : 14
    },
    { "_id" : 2,
      "name" : "C:27017",
      ...
      "pingMs" : 271
    }
  ],
  "ok" : 1
}
```
Tagging (version 2.0+)

Tagging gives you fine-grained control over where data is written. It is:

- Customizable: you can express your architecture in terms of machines, racks, data centers, PDUs, continents, etc. (in any combination or level that is important to your application).
- Developer/DBA-friendly: developers do not need to know about where servers are or changes in architecture.

Each member of a replica set can be tagged with one or more physical or logical locations, e.g., {"dc" : "ny", "rack" : "rk1", "ip" : "192.168", "server" : "192.168.4.11"}. Modes can be defined that combine these tags into targets for getLastError's w option.

For example, suppose we have 5 servers, A, B, C, D, and E. A and B are in New York, C and D are in San Francisco, and E is in the cloud somewhere.

Our replica set configuration might look like:

```json
{
  _id : "someSet",
  members : [
    { _id : 0, host : "A", tags : {"dc" : "ny"} },
    { _id : 1, host : "B", tags : {"dc" : "ny"} },
    { _id : 2, host : "C", tags : {"dc" : "sf"} },
    { _id : 3, host : "D", tags : {"dc" : "sf"} },
    { _id : 4, host : "E", tags : {"dc" : "cloud"} }
  ],
  settings : {
    getLastErrorModes : {
      veryImportant : {"dc" : 3},
      sortOfImportant : {"dc" : 2}
    }
  }
}
```

Now, when a developer calls getLastError, they can use any of the modes declared to ensure writes are propagated to the desired locations, e.g.:

```plaintext
> db.foo.insert({x:1})
> db.runCommand({getLastError : 1, w : "veryImportant"})
```

"veryImportant" makes sure that the write has made it to at least 3 tagged "regions", in this case, "ny", "sf", and "cloud". Once the write has been replicated to these regions, getLastError will return success. (For example, if the write was present on A, D, and E, that would be a success condition).

If we used "sortOfImportant" instead, getLastError would return success once the write had made it to two out of the three possible regions. Thus, A and C having the write or D and E having the write would both be "success." If C and D had the write, getLastError would continue waiting until a server in another region also had the write.

Below are some common examples and how you'd specify tags and w modes for them.

**Server X should have a copy.**

Suppose you want to be able to specify that your backup server (B) should have a copy of a write. Then you'd use the following tags:

<table>
<thead>
<tr>
<th>Server</th>
<th>Tags</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>{&quot;backup&quot; : &quot;B&quot;}</td>
</tr>
</tbody>
</table>

To define a mode for "server B should have a copy," create the mode:

```plaintext
backedUp : {"backup" : 1}
```

You want one server with a "backup" tag to have the write.

So, your config would look like:
```json
{
    _id : replSetName,
    members : [
        {
            "_id" : 0,
            "host" : B,
            "tags" : {"backup" : "B"}
        },
        ...
    ],
    settings : {
        getLastErrorModes : {
            backedUp : {backup : 1}
        }
    }
}
```

To use this mode in your application, you'd call `getLastError` with `w` set to `backedUp`:

```bash
> db.runCommand({getLastError : 1, w : "backedUp"})
```

In the following examples, we will skip the configuration and the usage for brevity. Tags are always added to a member's configuration, modes are always added to `getLastErrorModes`.

**Make n backups**

Suppose you have three backup servers (B1, B2, B3) and you want at least two of them to have a copy. Then you'd give each of them a unique "backup" tag:

<table>
<thead>
<tr>
<th>Server</th>
<th>Tags</th>
</tr>
</thead>
<tbody>
<tr>
<td>B1</td>
<td>{&quot;backup&quot; : &quot;B1&quot;}</td>
</tr>
<tr>
<td>B2</td>
<td>{&quot;backup&quot; : &quot;B2&quot;}</td>
</tr>
<tr>
<td>B3</td>
<td>{&quot;backup&quot; : &quot;B3&quot;}</td>
</tr>
</tbody>
</table>

Then you would create the mode:

```json
backedUp : {"backup" : 2}
```

**Make sure there are at least three copies of the data and it is present on at least two continents.**

All of the rules up until now have only had one condition, but you can include as many and-conditions as you want. Suppose we have the following:

<table>
<thead>
<tr>
<th>Server</th>
<th>Tags</th>
</tr>
</thead>
<tbody>
<tr>
<td>S1</td>
<td>{&quot;continent&quot; : &quot;nAmerica&quot;, &quot;copies&quot; : &quot;S1&quot;}</td>
</tr>
<tr>
<td>S2</td>
<td>{&quot;continent&quot; : &quot;nAmerica&quot;, &quot;copies&quot; : &quot;S2&quot;}</td>
</tr>
<tr>
<td>S3</td>
<td>{&quot;continent&quot; : &quot;nAmerica&quot;, &quot;copies&quot; : &quot;S3&quot;}</td>
</tr>
<tr>
<td>S4</td>
<td>{&quot;continent&quot; : &quot;Africa&quot;, &quot;copies&quot; : &quot;S4&quot;}</td>
</tr>
<tr>
<td>S5</td>
<td>{&quot;continent&quot; : &quot;Asia&quot;, &quot;copies&quot; : &quot;S5&quot;}</td>
</tr>
</tbody>
</table>

Then create a mode like:

```json
level : {copies : 3, continent : 2}
```

Note that modes can contain as many clauses as you need.
**Make sure at least two servers across at least two racks in nyc have it.**

This is a complication of our original example. The key concept here is that not all tags need to be present on all servers. For example, some servers below are tagged with "nyc", others are not.

<table>
<thead>
<tr>
<th>Server</th>
<th>Tags</th>
</tr>
</thead>
<tbody>
<tr>
<td>S1</td>
<td>{&quot;nycRack&quot; : &quot;rk1&quot;, &quot;nyc&quot; : &quot;S1&quot;}</td>
</tr>
<tr>
<td>S2</td>
<td>{&quot;nycRack&quot; : &quot;rk2&quot;, &quot;nyc&quot; : &quot;S2&quot;}</td>
</tr>
<tr>
<td>S3</td>
<td>{&quot;nycRack&quot; : &quot;rk2&quot;, &quot;nyc&quot; : &quot;S3&quot;}</td>
</tr>
<tr>
<td>S4</td>
<td>{&quot;sfRack&quot; : &quot;rk1&quot;, &quot;sf&quot; : &quot;S4&quot;}</td>
</tr>
<tr>
<td>S5</td>
<td>{&quot;sfRack&quot; : &quot;rk2&quot;, &quot;sf&quot; : &quot;S5&quot;}</td>
</tr>
</tbody>
</table>

Now our rule would look like:

```
customerData : {"nycRack" : 2}
```

**Notes**

The examples above generally use hostnames (e.g., "nyc" : "S1"). This isn't required, it's just a convenient way to specify a server-unique tag. You could just as well use "foo", "bar", "baz" or "1", "2", "3", or any other identifiers.

Do not use "*" or "$" in tags, these characters are reserved for future use.

### How Caching Works

See Caching

### Memory Mapped Files

Depending on the platform you may see the mapped files as memory in the process (see the Virtual Memory section below), but this is not strictly correct. If mapped files are counted as process memory, the `top` utility may show way more memory for `mongod` than is really appropriate for what is in physical memory.

The operating system manages the memory where the memory mapped files reside (depending on the OS, this is usually done by the virtual memory manager). You can usually see mapped files using a program like `free -lmt`.

Memory mapped files are shown under "cached" memory:
Windows

By bringing up the Task Manager you can see the process memory allocation for mongod.

In addition in the Performance tab the "cached" memory which represents the memory allocated by the memory mapped (data) files.

Virtual Memory Size

Virtual Memory includes the mapped memory files which can be much larger than the actual physical (or swap) available on your host. If journaling is enabled then the database files will be mapped twice leading to much higher virtual memory allocation than might be obvious.

It is important to remember that only a portion of the virtual memory number is really in physical memory. There are many utilities which will report memory usage as the virtual memory number which can be misleading.

Read below for more metrics about virtual memory allocation and how to detect related problems.

Swap

Since the database files are memory mapped and should constitute most of your mongodb memory usage it is very unlikely that mongod will ever use any swap space. The reason for this is because any of the memory mapped files can simply either be released from memory (without going to swap) to free memory for other programs or written back to the database files which means they never need to be "swapped" out to disk in the swap space (since they are already backed by files).

If you see continuous swap usage then it most likely means one of these things:

- Your system is extremely constrained by memory (see free -ltm "cached" to confirm)
- There is a memory leak (like the javascript engine, or lots of no_timeout cursors never being closed, or other internal data structures piling up)
- Some other program is stealing lots of memory

Always Have Swap

Because of these possible conditions it is always good to have some swap space available on your system. Think of the swap space as something like a steam release valve which allows excess pressure to release without blowing the system up.

Commands

The `serverStatus()` command provides memory usage information. Shell example:

```bash
skot@stump:~$ free -tm
```

<table>
<thead>
<tr>
<th></th>
<th>total</th>
<th>used</th>
<th>free</th>
<th>shared</th>
<th>buffers</th>
<th>cached</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mem:</td>
<td>3962</td>
<td>3602</td>
<td>359</td>
<td>0</td>
<td>411</td>
<td>2652</td>
</tr>
<tr>
<td>+/- buffers/cache:</td>
<td>538</td>
<td>3423</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Swap:</td>
<td>1491</td>
<td>52</td>
<td>1439</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Total:</td>
<td>5454</td>
<td>3655</td>
<td>1799</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
One can verify there is no memory leak in the mongod process by comparing the mem.virtual and mem.mapped values (these values are in megabytes). If you are running with journaling disabled, the difference should be relatively small compared to total RAM on the machine. If you are running with journaling enabled, compare mem.virtual to 2*mem.mapped. Also watch the delta over time; if it is increasing consistently, that could indicate a leak.

The mem.mapped value reflects the size of all databases currently open. When replication is on, this includes the size of the local database which includes the oplog. When journaling is enabled each file is mapped twice, once as a writable memmapped view and once as a protected view. The total amount of RAM used is roughly the same; the larger virtual memory size should not be a cause for concern.

One large component of the difference between mem.virtual and mem.mapped (or 2*mem.mapped when journaling is enabled) can be stack memory. In particular, each connection that you have open has a stack frame. The size of each stack frame is determined by the stack size; in Linux this typically defaults to 8MB, which means that each connection will use 8MB on the server. If you are using many connections and are concerned with memory usage you should reduce the stack size to 1MB (this is automatic in the upcoming v2.0 release).

On Linux, extra_info will contain information about the total heap size in a heap bytes field.

You can also see the virtual size and mapped values in the mongostat utility’s output.

While increasing virtual size can indicate a memory leak, increasing resident size (ie, what is reflected as RES in the output of top) indicates that the operating system is using a larger portion of available memory to hold mongodb data, which often occurs under normal operations as a system warms up.

Note: OS X includes the operating system image in virtual size (~2GB on a small program). Thus interpretation of the values on OS X is a bit harder.

**Working Set Size**

In MongoDB it is fine if databases (and thus virtual size) are much larger than ram (terabytes for example); however, you will want your working set to stay in memory to achieve good performance. Otherwise lots of random disk IO’s will occur, and unless you are using SSD, this can be quite slow. One area to watch specifically in managing the size of your working set is index access patterns. If you are inserting into indexes at random locations (for example, with id’s which are effectively randomly generated by hashes), you will continually be updating the whole index. If instead you are able to create your id’s in approximately ascending order (for example, day concatenated with a random id), all the updates will occur at the right side of the b-tree and the working set size for index pages will be much smaller.

**Eatmem utility**

Measuring working set size can be difficult; even if it is much smaller than total RAM, if the db has been up for a while and the db is much larger than RAM in total, all memory will be indicated as in use for the cache. Thus we need some other way to estimate our working set size.

One technique is to use a utility which reserves a certain amount of system memory for itself. So one could run this with a certain amount specified and see if the server continues to perform well. If not, the working set is largely than (total_ram - eaten_ram). Note this test will eject some data from the file system cache which may take time to page back in after the eatmem utility is terminated.

Running eatmem continuously with a small percentage of total RAM (say, 20%) is a good technique to get an “early warning” of memory being too low. If disk i/o activity increases significantly, terminate eatmem to mitigate the problem for the moment until further steps can be taking.

**Asymmetry**

In replica sets if one server is underpowered this could one again help as an early warning mechanism for server capacity. Of course the server must be receiving representative traffic to get an indication here.

**Unix Utilities**

mongod uses memory-mapped files; thus the memory stats in top require interpretation in a special way. On a large database, virtual bytes/VSIZE will tend to be the size of the entire database, and if the server doesn’t have other processes running, resident bytes/RSIZE will be the total memory of the machine (as this counts file system cache contents).

vmstat can be useful – try running vmstat 2. on OS X, just vm_stat.

**Padding Factor**
Overview

When you update a document in MongoDB, the update occurs in-place if the document has not grown in size. If the document did grow in size, however, then it might need to be relocated on disk to find a new disk location with enough contiguous space to fit the new larger document. This can lead to problems for write performance if the collection has many indexes since a move will require updating all the indexes for the document.

Mongo adaptively learns if documents in a collection tend to grow, and if they do, it adds some padding so that the document has room to grow. This helps to prevent excessive movements on subsequent writes. This statistic is tracked separately for each collection.

You can check the collection's current padding factor by running the `db.<collection-name>.stats()` command helper in the shell. The padding factor indicates what the padding will be for new record allocations (for inserts or updates that grow a document, they cause a move operation to a new location).

```
> db.coll.stats()
{
    "ns" : "...", ...
    "paddingFactor" : 1, ...
    "ok" : 1
}
```

As each document is written at a different point in time the padding for each document will not be the same. Also, as the padding factor is relative to the size of each document you cannot calculate the exact amount of padding for a collection based on the average document size and padding factor.

The padding factor is 1.0 if there is no padding. 1.5 would indicate 50% padding on a new insert/moves.

**No padding after imports, repairs, compactions and initial replica syncs**

After compaction, repair and import operations, there is (generally) no padding as they were inserted and there were no updates (which would cause the paddingFactor to change). Thus you may see slower update performance after these cases, but the size required for storage will be lower.

**Shrinking Documents**

If a document gets smaller (e.g., because of an `unset` or `pop`), the document does not move but stays at its current location. It thus effectively has more padding. Thus space is never reclaimed if documents shrink by large amounts and never grow again. To reclaim that space run a `compact` operation (or repair).

**usePowerOf2Sizes**

v2.2+

Setting this attribute for a collection will round up allocation sizes to powers of two, resulting in much less potential for fragmentation (some extra disk space will be used for the collection's documents; the collection's index sizes will be unchanged). You can set this attribute with the `collMod` command.

```
> db.runCommand( { collMod : collectionname , usePowerOf2Sizes : true } )
```

**Manual Padding**

Padding in MongoDB is automatic. You should not have to do so manually. In exceptional cases one can do this though. The strategy is to add a faux field that assures allocation of a larger slot size for the document. The faux field is then removed; at this point there is extra room for expansion on a future update. Example below.

It is usually easier to use the v2.2 `usePowerOf2Sizes` attribute instead of manually padding.
> function checkOk() { assert( !db.runCommand({getlasterror:1,j:true,w:2,wtimeout:5000}).err ); }  
> 
> t = db.zcollection; 
> db.setProfilingLevel(2); 
> 
> // let variable b be a very long string 
> t.insert({q:1}) 
> t.update({q:1},{$set:{yy:b}}) 
> checkOk() 
> 
> // note the "moved:true" in the output below -- indicating not enough 
> // padding to avoid moving a document. 
> db.system.profile.find() ... 
> ... 
> 
> // not important what value of 'padding' is, only its length: 
> t.insert({q:2,padding:ourpaddingstring}) 
> t.update({q:2},{$unset:{padding:1}}) 
> t.update({q:2},{$set:{yy:b}}) 
> checkOk() 
> 
> // no "moved:true" below (which is good). Note however that the automatic adjustment 
> // of a collection's padding factor normally achieves this regardless. Manually padding 
> // is rarely necessary. 
> db.system.profile.find() ... 
> 
> See Also

### Production Deployments

MongoDB can be used for a lot of different projects; the goal is for it to be a fairly general purpose tool. As you can see, many of the use cases are online or operational databases in which someone is writing an application in front of the database. Business intelligence / analytics use is not unusual but usually more specialized. For example, real time dashboarding is highly popular, and when the data set gets really big, things can make a lot of sense. See the use cases page for more on this and for more on when you wouldn't use it.

If you're using MongoDB in production, we'd love to list you here! Please complete this web form and we will add you.

Yabblr uses MongoDB for everything, including inventory management and orders. Yabblr is an E-commerce platform that flips ‘deals’ on its head. Instead of pushing random offers at you, Yabblr empowers you to group together with friends to pull deals on products you select. Yabblr uses MongoDB exclusively as a data store for the entire platform, including:
- User data
- Real-time metrics used for analyzing user behavior and system health
- Inventory management
- Customer orders
- Event queues and message bus between different systems.

Ordoro uses MongoDB to store orders, inventory, and suppliers. Ordoro deals with everything that happens after a shopper clicks checkout on the retailer's website: print packing lists and shipping labels, manage inventory levels, manage dropshipping, manage customers, manage suppliers, etc. Ordoro is the backoffice control panel for SMB retailers.

SavingStar uses MongoDB to store our coupon content and service metadata, as well as all of our coupon activation data. The company is the first national, fully digital, eCoupon service, available for free. There's nothing to clip, nothing to print.
Wedding Paper Divas uses MongoDB to store our categories and products. The company allows users to create custom wedding invitations online using their personalization tools to make unique and trendy wedding invitations quickly and easily.

Storeden is a cloud solution totally based on MongoDB. The easiness of the most popular shopping websites meets the performance of an advanced online solution. Storeden is a revolutionary e-Commerce platform that allows individual users and web-agencies to set up amazing online stores in just a few clicks. Every user has the chance to create and sell applications, graphic themes, and "suites" in the Cloud. Storeden can be perfectly integrated with the most common ERP and CRM platforms, allowing each user to effectively leverage on Facebook, Ebay, Shopping, and Kelkoo as further sales channels. Storeden is natively optimized for SEO.

Gittigidiyor.com is the biggest e-commerce site in Turkey with more than 7 million registered users. Gittigidiyor.com have a big replicated and shard MongoDB cluster for storing and for caching a wide range of data.

iPara uses MongoDB payment pages to log kind of user activities logging, they analyze logs to determine new designs and process. iPara offers safe and convenient payment discount campaigns, providing many advantages for both users and businesses.

Coinbase uses MongoDB for their primary data for their web app, api requests, etc. Coinbase is a decentralized digital currency that is changing the world of payment.
local.ch uses MongoDB as their central data store to serve complete documents for all of their phonebook entries and geo data is consumed by the www.local.ch as well as their mobile apps.

Turkishexporter.net uses MongoDB to list and their products, company and leads.

Bestcovery.com uses MongoDB for MyBest pages, which allow users to discover interesting products and curate their own favorite products and services to share with the world.

Bestekortingscode.nl uses MongoDB as their primary database.

Wish is a social platform helping connect consumers to merchants with great deals on the products they want. They use MongoDB as their primary data store to serve up hundreds of gigabytes of data to almost 10 million users in real-time. It stands behind every feature on the site, from their personalization engines to their commerce platform, and supports their growth of millions of new users every month.

Boundless Learning uses MongoDB as a rapid-prototyping technology to develop a robust content management system.

Foothill-De Anza Community College District migrated a problematic document storage system into a web application backed by MongoDB, and using the Mongo GORM plug-in for Grails. They have indexed (and stored with GridFS) over 300,000 documents (56GB) into a single Mongo database. Mongo is much easier to get online than a comparable RDBMS, and the rich feature set helped significantly reduce the amount of required application coding. All said and done, switching to Mongo for this project has been a big win.

Email

Sailthru is an innovative email service provider that focuses on improving the quality of emails over quantity. Moving to MongoDB from MySQL allowed us extreme flexibility in providing an API to our clients. Passing in arbitrary JSON data is easy – our customers can use objects and arrays inside of their emails. And we've launched Sailthru Alerts, which allows our customers basically whitelabeled Google Alerts: realtime and summary alerts (price, tag match, etc) that are completely up to the customer due to our schema-free data storage. Also, we can gather realtime behavioral data on a client's signed-up users (tag-based interests, geolocation, time of day, etc), and use all that information to power dynamically assembled mass emails that get higher click-through rates than static emails. Plus we just launched an onsite recommendation widget (check it out at refinery29.com), and we're using MongoDB's analytic capabilities to rapidly A/B test different behavioral algorithms.

MongoDB is being used for the game feeds component. It caches game data from different sources which gets served to [ea.com](http://ea.com), [rupture.com](http://rupture.com) and the EA download manager.

Kano Games uses MongoDB to build an online gaming web app that integrates social elements. It is a gaming web app that offers a large collection of html5 and flash games with new ones added daily. MongoDB is used to store all persistent data at Kano Games. Reliability, scalability, performance, redundancy and flexibility were all considered when selecting a persistent storage solution and MongoDB beat out the competition as it best fit Kano Games needs.

Shadelight is a unique fantasy roleplaying game where you play one of the legendary Guardians of Elumir. Set out on magical quests, battle mysterious creatures and explore a truly unique fantasy world.
Free rice is developed by World Food Programme, the largest UN humanitarian organisation. Freerice.com is a social quizz-like game where each good answer to a question make you win 10 rice grains. Since the beginning more than 85 billions of rice grains were won through freerice. Fully connected with twitter, facebook and groups, freerice tracks down each gain of each person. This generates almost 1 MongoDB row for each right answer, which mean 8 billions of rows currently stored in Freerice MongoDB. Numerous totals are provided to the end user, which are all stored in Mongo too.

Lichess.org uses MongoDB to store more than 3 million chess games. It also contains the analysis, users, forum posts and chat messages. Lichess.org needs blazing fast updates and efficient indexing; mongodb gives it both. Lichess.org is OpenSource! Check the code on http://github.com/ornicar/lila.

MongoDB is the database behind Moshen Limited’s Facebook game Gambino Poker. MongoDB is used to store all game events and player profiles. We use a 3 node replica-set and RAID 10 EBS Volumes.

Hitcents uses MongoDB for primary data storage for their iOS/Android app PictureTHIS. The app is a cooperative social word game.
Gamera Labs uses MongoDB for the Real-Time game High5Poker. The app is a cooperative social word game. MongoDB is used in production for data storage like players information and statistics.

Doodle or Die uses MongoDB for almost everything in their online drawing game, including game and player information. Their logging and error tracking is also done through Mongo. More can be found in the MongoDC presentation Mongo or Die.

**Government**

The National Archives (UK) made details of 11m records available through an application interface it published as part of an ongoing programme to get more official records online. It is consolidating numerous existing electronic archives, either by porting them directly or putting them in a service wrapper that can communicate with its unified system. The unified system uses MongoDB and is built on a Microsoft software stack.

- National Archives releases public application programming interface for 11m records - ComputerWorld (Sept 2011)
- From SQL Server to MongoDB - Presentation at MongoDB UK (Sept 2011)

The British Government launched a beta of its GOV.UK platform, testing a single domain for that could be used throughout government. According to James Stewart, the Tech Lead on the beta of GOV.UK, "We started out building everything using MySQL but moved to MongoDB as we realised how much of our content fitted its document-centric approach," said Stewart. "Over time we've been more and more impressed with it and expect to increase our usage of it in the future."

- Colophon for the GOV.UK beta - Feb 2012
- With GOV.UK, British government redefines the online government platform - O'Reilly Radar (Feb 2012)
Sunlight Labs is a community of open source developers and designers dedicated to opening up our government to make it more transparent, accountable and responsible. MongoDB powers the National Data Catalog and the Drumbone API, which is an aggregator of data about members of Congress.

- MongoDB at Sunlight - Luis Martinez’s Presentation Slides
- Civic Hacking - Video from Luigi Montanez’s presentation at MongoNYC (May 2010)
- How We Use MongoDB at Sunlight blog post (May 2010)

In addition, MongoDB has been used for various projects at the federal, state, and city levels in the U.S.

Note: If you are in Washington D.C. area, be sure to check out the annual Mongo conference there (“MongoDC”), as well as local mongo user groups.

### Healthcare

<table>
<thead>
<tr>
<th>Company</th>
<th>Use Case</th>
</tr>
</thead>
<tbody>
<tr>
<td>Santosoft</td>
<td>Santosoft uses MongoDB for virtually 100% of its data related stack. They run a fully blown shard cluster for transactional data, as well as analytics. They are building apps and tools for MongoDB and also hope to build the largest common care database globally.</td>
</tr>
<tr>
<td>HolaDoctor</td>
<td>HolaDoctor.com is the most comprehensive health and wellness portal available in Spanish for the global online Hispanic community. MongoDB is being used to store all the content for the site, including GridFS to store article images. Session data is also being persisted on our MongoDB cluster using a custom PHP save handler.</td>
</tr>
<tr>
<td>Vitals.com</td>
<td>Vitals.com consolidates and standardizes doctor and other health provider data from over 1,000 sources to help users make informed health care choices. Our technology also powers the websites and backends of insurance companies, hospitals, and other health information brokers. In early October, we switched the datasource for our Find A Doctor location-based search functionality from PostgreSQL to a geo-indexed MongoDB collection. Since then, searches are now five to ten times as fast, and the decreased load on our dataservers permits us to serve more clients. Based on this success, we are transitioning other functionality to MongoDB datasources.</td>
</tr>
<tr>
<td>TalkAboutHealth</td>
<td>TalkAboutHealth matches people with similar health concerns for answers and live chats. Meet others just like you, learn from experienced peers, and share your experiences.</td>
</tr>
<tr>
<td>Earlydoc</td>
<td>Earlydoc models medical data, which means things like master-identity management and data normalization occupy a lot of development time: this, specifically, is where the schemaless design of MongoDB is a huge win.</td>
</tr>
<tr>
<td>D Sharp</td>
<td>D Sharp uses MongoDB to store detailed medical observations and perform complex analysis to help people with diabetes better manage their blood sugars. Built using the Express web framework for Node.js and JQuery Mobile, D Sharp is the only diabetes application that support all types of diabetes on any modern smartphone or browser. This includes iPhone, iPad, Android, Windows Mobile, Blackberry and desktop browsers.</td>
</tr>
<tr>
<td>Vigilant Medical</td>
<td>Vigilant Medical uses MongoDB to manage the large, complex, and often sparse metadata surrounding medical images. MongoDB also provides the entire administrative backbone of Vigilant's enterprise web application, ImageShare.</td>

Mini Medical Record is designed to improve medical care. While designed to help everyone, it is especially useful for travelers, and others who may receive care through multiple medical systems. Whether paper or electronic, medical records in cutting edge hospitals are often geared more for billing and medicolegal protection. Critical up-to-date information may be very challenging to discover. In addition, even simple information like emergency contact phone numbers and latest medication lists, may be inaccessible for patients who seek care in settings where they do not routinely receive their care. Mini Medical Record alleviates those issues.
Shutterfly is an Internet-based social expression and personal publishing service. MongoDB is used for various persistent data storage requirements within Shutterfly. MongoDB helps Shutterfly build an unrivaled service that enables deeper, more personal relationships between customers and those who matter most in their lives.

Forbes has been around for nearly 100 years and on the web for more than a decade; recently, the media space has been a changing landscape. One of the changes that Forbes has undertaken starting in 2010 was the “opening up” of its digital and print platforms to a global collection of content creators, marketers, and audience members. This necessitated the changing of how the site worked, allowing content to flow easily through the site.

Forbes began to evaluate how they store and serve their content and decided to use MongoDB. They are currently using MongoDB for storing articles and company data and are working to move more of their core assets onto it.

| **AK®** | Aggregate Knowledge is an IaaS company that combines data management and multi-touch attribution to make media accountable helping advertisers, agencies, ad networks, DSPs, SSPs, and publishers manage and exploit all of their data around a single view of the user. With more data to process, and less time at hand, Aggregate Knowledge pairs MongoDB with Fusion-io flash memory solutions for a winning combination. |
| **MediaMath** | MediaMath is the leader in the new and rapidly growing world of digital media trading. |
| **Konverta.ru** | Konverta.ru is the first Real Time Bidding (RTB) ad exchange on the Russian and CIS online advertising market. MongoDB is used to store all ads, ad impressions, clicks, and other data, as well as for real-time reporting and optimization. |
| **G5** | G5 is the largest and fastest growing provider of vertical-specific local marketing solutions that help mid-market companies get found online, generate more qualified leads, convert more leads into new customers, track marketing performance - including offline, and optimize to the marketing sources with the best return on investment. G5 migrated its analytics platform from MySQL to MongoDB due to the heavy demands of storing & processing analytical data. MongoDB has proven to be fast, scalable, flexible, & maintainable. Best of all, MongoDB is supported by a fantastic community! |
Yodle uses MongoDB to persist queues of items to be synchronized with several partner APIs. Mongo is ideally suited for this update-heavy performance sensitive workload.

The Localstars platform makes it easy for local advertisers to build and manage locally targeted advertising campaigns. The new Localstars advert server cluster uses sharded MongoDB to provide super high performance real time ad serving decision making and campaign statistics.

EveryScreen is built on a scalable, high-performance, real-time mobile advertising bidding platform in Amazon EC2.

Rafflecopter is a web app that helps online publishers run sweepstakes on their own blogs & other sites. Rafflecopter logs and stores every entry to every contest that’s ever been run, all contest details, user profiles, various logs/metrics, etc.

LocalEver is a location based online market place to buy, sell & rent residential/commercial properties, automobiles, and a host of other products. MongoDB is the backbone of the system, which powers the whole range of features from geo spatial search to caching.

### Online Collaboration

<table>
<thead>
<tr>
<th>Company</th>
<th>Use Case</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Trello</strong></td>
<td>Trello is a collaboration tool that organizes your projects into boards. In one glance, Trello tells you what's being worked on, who's working on what, and where something is in a process. Trello stores all historical and non-ephemeral data in MongoDB. The Trello team was attracted to MongoDB for its speed. MongoDB offers very fast writes, faster reads, and better denormalization support — it allows them to store the data of each individual card on the Trello board in a single document in the database and still have the ability to query into (and index) subfields of the document. They were also attracted to MongoDB's reliability: it is really easy to replicate, back up, and restore. Other benefits for the Trello team: using a loose document store makes it easy to run different versions of the Trello code against the same database without fooling around with DB schema migrations. This has a lot of benefits when they push a new version of Trello; there is seldom (if ever) a need to stop access to the app while we do a DB update or backfill.</td>

**BuzzFeed** is a trends aggregator that uses a web crawler and human editors to find and link to popular stories around the web. BuzzFeed moved an analytics system tracking over 400 million monthly events from MySQL to MongoDB.

**uberVU** is an intuitive social media management and analytics service used by companies of all sizes in 20+ countries. uberVU uses Mongo as its primary data store because of its fast writes, its schemaless approach and reliability.

- **Intelligent Stream-Filtering using MongoDB** - Mihnea Giurgea’s Presentation at MongoUK (September 2011)
CopperEgg is able to achieve its super real-time updates and alerts of the RevealCloud product with the help of MongoDB. Mongo was the only DB that fit the requirements of extremely rapid storage and retrieval of customer monitoring data to provide on-screen updates every few seconds (NOT minutes). CopperEgg monitors thousands of end points world-wide in real-time. RevealCloud is available to application development organizations to give the instant visibility of system performance in any stage of the development lifecycle, from initial design through production, helping ensure SLAs…and giving your customers the response times they expect – right now.

Loggly uses MongoDB as a repository of statistics and summary information for time series log data. Loggly collects and stores metrics into MongoDB including the size and count of log events, and the results of saved searches run against our customized fulltext search engine based on SOLR. These metrics are used to drive graphs, reports, dashboards and exciting visualizations for users.

Pattern Builders built a .NET based streaming analytics engine using MongoDB. Relational databases and MSMQ were integrated with MongoDB for high performance and a great user experience.

Go Graph Stock Photography offers over 7 million stock images and graphics. We use MongoDB to track impression data on our search results pages. It helps us to track which results are served when a user does a search query. Using that data we are able to get a better idea of what our customers are looking for, and we are able to serve up better results which will translate into a better overall user experience.

VinTank uses MongoDB to power the analytics and reporting for their social media listening and social CRM features. The company is the only digital think tank for the wine industry.

PeerPong discovers everyone's expertise and connects you to the best person to answer any question.

We index users across the entire web, looking at public profiles, real-time streams, and other publicly available information to discover expertise and to find the best person to answer any question.

("I build, I bond") is a social network using MongoDB for its dashboard feeds. Each feed is represented as a single document containing an average of 1000 entries; the site currently stores over two million of these documents in MongoDB.

is a new way to discover YouTube videos that people are talking about on Twitter. Zoofs camps in Twitter searching for tweets with YouTube video links, and then ranks them based on popularity.

is an online classifieds marketplace that serves up more than 15 million visits a month and is the company behind the popular Oodle is using Mongo for storing user profile data for Facebook Marketplace and has also open sourced its Mongo ORM layer

relaunched using the MongoDB and MongoMapper. Read the Funadvice CTO's post to from May 2010 for more details.

MongoDB User Forum is using MongoDB for the backend storage of business listings. Yasabe.com is the first local search engine built for Hispanics in the US with advanced search functionality. You can find and discover more than 14 million businesses via the web or your mobile phone. All the information is in both Spanish and in English.

is a Fantasy Soccer Portal recently launched for the World Soccer Cup: South Africa 2010. Mongo has been used entirely to store data about users, groups, news, tournaments and picks. It uses the PHP driver with a Mongo module for Kohana v3 (Mango).

switched over to MongoDB 1 year ago after exhausting other cloud and relational options. As a contextual affiliate network, Kehalim stores all of its advertisers, ads and even impressions on top of MongoDB. MongoDB has outed both MySQL and memcached completely and also provides great hadoop-like alternative with its own map-reduce.

is an e-commerce music site that allows people to buy beats (music instrumentals) produced by some of the best producers in the world. Now we entirely use MongoDB to store users profile, beats information, and transaction statistics.

, a search engine for chemical properties, is built on top of MongoDB. For a fairly extensive explanation of the tools and software used and some MongoDB tips, please go to chemeo.com/doc/technology.

is a place were you can read all your favourite websites in one place. MongoDB has replaced MySQL for the storage backend that does all the heavy lifting and caching of each website's news feed.

 Powered by MongoDB - SamLown.com (June 2010)
| **ChinaVisual.com** is ChinaVisual.com mc major production and development.

| **RowFeeder** is an easy social media monitoring solution that allows people to track tweets and Facebook posts in a spreadsheet. RowFeeder uses MongoDB to keep up with the high volume of status updates across multiple social networks as well as generate basic stats.

| **Open Dining Network** is a restaurant data and food ordering platform that provides a RESTful API to take web and mobile orders. MongoDB is used to manage all restaurant, customer, and order information.

| **URLi.st** is a small web application to create and share lists of links. The web application is coded in Python (using the pylons framework) and uses MongoDB (with pymongo 1.6) in production to power its data layer.

| **Kidiso** is a safe online playground for children up to 13, with advanced parental controls. In the current setup, we are using MongoDB for logging, analysis tasks, and background jobs that aggregate data for performance (ie search results and allowed content).

| **Carbon Calculated** provides an open platform that aggregates carbon and greenhouse gas emissions for everything in the world, from passenger transport, raw materials, through to consumer goods. Built on top of this platform, Carbon Calculated offers a suite of products that make carbon calculation accessible and intuitive.

| **Vowch** is a simple platform for telling the world about all the people, places and things that matter most to you. It is a platform for making positive, public endorsements for anyone or anything from a Twitter account.

| **Ros Spending** is the first Russian public spending monitoring project. It includes information about 1,400,000 federal government and 210,000 regional government contracts, as well as information about more than 260,000 suppliers and 26,000 customers. MongoDB stores all reports, customer and supplier information, stats and pre-cached queries. The project was initiated by the Institute of Contemporary Development and launched publicly in July 2010 during the Tver economic forum.

| **BlueSpark** designs and develops iPhone and iPad applications and specializes in Adobe Flash development, we have a passion for creating great user experiences and products that feel simple to use.

| **Aghora** is a time tracking application specially designed for the requirements of the Brazilian governmental requirements. Our whole application is based on PHP and MongoDB.

| **Man of the House** is the real man's magazine, a guide for the jack of all trades trying to be better – at work and at home, as a father and as a husband. The entire backend of the site depends on MongoDB.

Mashape is a frustration-free online storefront for developers who want to consume or generate and distribute an API of any kind of service, either an open source project.

How We Switched from Hibernate to MongoDB in a week with Morphia
- Marco Palladino's Presentation at MongoSF (May 2011)

The UK Jobsite is an easy to use job board allowing users to quickly search and apply for job vacancies. We use MongoDB for all aspects of the site - in its entirety it fully runs the awesome MongoDB from job searches to user information, everything is kept in documents. For more information we have written a few of the reasons we chose MongoDB and continue to use it in a full production site - this can be found at http://www.theukjobsite.co.uk/tech.php.

Tastebuds music dating lets you meet like-minded single people who share your love for music. Users can connect with their last.fm username - or simply enter a couple of their favourite artists - and are immediately shown single people who share their musical preferences. Tastebuds is also integrated with popular events service Songkick.com allowing users to arrange to meet up at concerts they're attending. MongoDB has dramatically increased the speed at which we can search our database of artists. This allows users to rapidly select their preferred artists using our homepage artist autocomplete.

Skimlinks enables publishers to easily monetise online content by converting normal product links into equivalent affiliate links on the fly and via SkimWords will create relevant contextual shopping links to products mentioned in the content. Bringing together more than 25 affiliate networks and over 12,000 retailer programs in one place, Skimlinks makes affiliate marketing a viable mainstream business model and ensures no money is left on the table. We use Mongo to log and report on the almost 2 Billion impressions we get every month.

VanillaDesk is an ITIL based servicedesk/helpdesk solution provided as SaaS. MongoDB is used as the main database engine to store all tickets, configuration items, customer and contact details. MongoDB's document-oriented approach and high-availability model supported by replica-sets is exactly what enables VanillaDesk to process records fast and keep them safe and available.

Summify uses MongoDB (metadata and HTML only) as the main database, MongoDB's document-oriented model supports the fast searching and indexing that we require. MongoDB allows us to keep only the most recent 1000-5000 news stories for each user. Besides this, we also use MongoDB as a cache for URL redirects and Twitter user information (usernames, scores, etc.).

Kapost's online newsroom technology enables our users to manage a large group of contributors to produce content. We use MongoDB to store all the data that our users create and provide performance analytics for the newsroom content.

ContactMe is a light customer relationship management (CRM) tool designed for small businesses. For many small businesses, enterprise CRM solutions are too cumbersome and technically demanding; ContactMe.com aims to fix this. Besides providing free contact forms and buttons for websites, blogs, and social media sites like Facebook, ContactMe consolidates all of a user's leads and contacts into one place, making for easy and efficient contact management.

Moontoast Impulse is a free Facebook application that lets fans play, share, and purchase music right from a Facebook fan page. Their tools power communities, stores, and private sales clubs that open the doors to a world of new fan-building and revenue-generating opportunities. Moontoast leverages the following technologies in Moontoast Impulse: MongoDB, PHP 5.3, Zend Framework, Doctrine 2, jQuery, Gearman, Ruby, MySQL, and more. Moontoast uses MongoDB to store all product and file system data for Moontoast Impulse.

Shopperhive is a social price comparison shopping site providing comprehensive search, social product reviews, video reviews and the cheapest prices online. Shopperhive uses MongoDB as a highly scalable data back-end storage.
**tracknose** develops location-based applications for mobile phones that detect your GPS position and track nose reward you with discount vouchers when you enter a retail outlet that is part of the scheme. MongoDB was chosen for excellent scalability and capacity to manage geospatial indexes, facilitating the generation of georeferenced statistics.

**Wusoup** is a free online application for meeting interesting people outside of your social circle. MongoDB handles all user and message data, along with all analytics that power the Wusoup algorithm.

**Fave** is a local search application designed to help people find and communicate with their favorite businesses, and to help businesses expand their presence on major search engines. Soon, Fave will be releasing next-generation mobile applications to help its audiences harness the power of geo-aware web services. Infrastructure/architecture containing 14+ million business records; strong emphasis on performance/response time; attempting to leverage flexibility to deliver bulk daily ads/deals and pay per call campaigns.

**Doodle** is the world's leading consensus-scheduling service with millions of users worldwide. We use MongoDB as an addition to MySQL and plan to slowly but steadily persist more data via MongoDB and less data via MySQL.

**FindTheBest** is an objective, socially curated comparison engine that allows you to find a topic, compare your options and decide what's best for you. Ultimately, FindTheBest allows you to make faster and more informed decisions by allowing you to easily compare all the available options, view expert ratings on products and services and read and write reviews on millions of listings. FindTheBest uses MongoDB for traffic monitoring and analysis as well as storage of user reviews.

**Fuseware** provides realtime analysis into social networks, blogs, forums, review sites, multimedia sites and more. This analysis is structured for easy understanding and dissemination by company decision makers. We use MongoDB clusters to provide scalable data storage for the myriad different web objects that we store. We have hundreds of gigabytes of stored data, and MongoDB allows us full horizontal scalability and data access.

**Wherevent** is a search engine for geolocated events. It helps people finding local events in their area or in other cities. The entire database is based on a MongoDB sharding. We especially use the geospatial feature.

**Skyline Innovations** develops and finances distributed renewable energy projects for small businesses. We deploy custom monitoring solutions to maximize the energy production and efficiency gains. We use MongoDB for data warehousing and fast, flexible multidimensional analyses of our real-world data.

**Memrise** combines the art and science of memory to turbocharge learning. We love using MongoDB for all of our learning and web analytics, and any time we want to be able to prototype rapidly without worrying about schema ossification.

**Dather** is a content platform that assembles all of your content by events into an interactive timeline. You can invite friends, family, fans, etc... to join your timeline and contribute their own media and events.
Fundastic.info is CrunchBase data + visualization. It offers a graphical way to visualize funding by investors and financial organizations implemented using the Crunchbase API. Fundastic provides dedicated pages for each investor and financial organization and provides various charts to help understand the investment pattern of an investor or financial organization. Fundastic.info uses MongoDB to store all its investor and financial organizations funding data and performs aggregations on it. Data is stored in MongoDB as JSON documents and integrates seamlessly with Javascript.

Foofind Labs is a universal search engine. In Foofind we work creating software that crawls every network and indexes every file. This way, we intend to offer the largest collection of links available. Foofind is a creation by Pablo Soto, P2P technology designer, developed in Madrid, Spain by MP2P Technologies. MongoDB is used to store all the data on the site. This includes several million files, indexed with Sphinx in order to allow text search.

Beaconpush is a cloud service for push messaging in the browser. Enables any web site to integrate real-time data with a few lines of JavaScript. Supports native Web Sockets with a wide array of fallback methods for older browsers. Beaconpush uses MongoDB to store all message statistics - in real-time. This data is used for presenting reports, charts and statistics for each user. MongoDB handles this with a very low system impact and has proven very efficient for this kind of data storing.

Easy Bill, India's first to the life of the com never-before converter biggest problems fac enterprises for bill ps grown exponentially, activity logging of ou.

DeskMetrics is a real-time analytics service for desktop software that enables developers to understand how their users are using their applications. How many are installing, uninstalling, executing their application, where are the users from and help developers to solve bugs by analyzing the exceptions that happened on the user's machine.

We use MongoDB to store all data gathered from the users applications and all generated reports. We have chosen MongoDB most because of its simplicity, specially to shard the collections. Shards are very important for us since we collect and analyze a lot of data.

Interstate provides b tasks using awesom data, etc).

Proxlet helps you fig a Twitter API proxy, way of browser exte per-user setting doci designed to scale hc

A Beautiful Marriage: MongoDB and node.js - Chris Ricca's Presentation at MongoNYC (June 2011)

Dayload provides a hassle-free AWS Usage Monitoring. We aggregate customer's AWS resource usage and CloudWatch monitoring logs into MongoDB and deliver daily statistics as a HTML mail. Storing AWS resource usage and CloudWatch monitoring logs. Analyzing data with JavaScript MapReduce function.

Avivo is creating modern Identities, Brand design concepts and delivers superb service in a form of touch, mobile, web and custom made solution for LOB (line of business) that enhance user digital experience. Through design and branding processes we help our clients to move from static world into digital world of interaction. Ultimately we are delivering engaging software and custom made applications to our clients that build brand loyalty and helps them to innovate. Our passion for design and commitment to innovation is leading us to dive deeply into research and development with new technologies to brings out the very best for our clients. We are multinational team that lives and works in Ljubljana, Slovenia. MongoDB is the primary database for all of our generated links and tracking statistics.
Abusix is the network and email abuse handling specialist providing network abuse reporting, customized Abusix spamfeeds (www.spamfeed.me), consulting and tools against network abuse for ISPs, ESPs and technology providers. We know about the needs network operators and Internet Service Providers have today, while handling behavior in their network by handling thousands of incoming complaints and millions of incoming datasets about abusive behavior in their network manually, but still not solving blacklistings and reputation problems. There is a major need for a solution that handles all these information in a semi or fully automatic way in order to increase customers security and satisfaction, increase infrastructure security and performance, free resources in abuse departments for real anti-abuse work and minimize customer care costs. We use the MongoDB in environments where we need a fast and scalable storage solution which is easy to access. It almost suits all needs and it is fun to work with.

Idea2 is a versatile, customizable data management application. Our platform easily allows anyone to create and implement a hosted business management solution that connects customer relationships, projects, customer care and support, business intelligence, and document management in a browser-based, fully application and work transition, we also created a better user experience for our clients due to improved application response.

FamilyTies is family networking - like social networking but designed to make connecting extended families and friends of families easier. Profiles for households and each household member including children under 13, basic family trees, photo sharing, blogs, comments and birthday reminders with much more to come. Mongo is used to store http sessions, photos, the operational data, logs, audit trails and various cache objects that speed up frequently needed expensive to compute data like family trees and relationship maps.

Pracanowo.pl is a job portal that helps people create online resumes that can be saved into different formats and finds jobs based on experience listed. MongoDB is used to store user account information and in few months to store job postings and board information.

Republika Online is the online version of "Harian Republika", a national newspaper. We use sharded MongoDB as storage of all news and comments.

Grepler.com is a distributed open system that merges several newsgroups, groups, forums and mailing lists to enable single point of access and discussions. Everything is now running from MongoDB except the user accounts which will be mapped in near future.

Thuisvergelijken.nl is the biggest Islamic news portal in Indonesia. It's an online version of "Harian Republika Online", a national newspaper. We use sharded MongoDB as storage of all news and comments.

CHECK24 is one of Germany`s leading price comparison websites. On CHECK24.de customers can compare a wide range of products from the fields of insurance, money, energy, telecommunications, and travel and thus save hundreds of Euros per year. In contrast to most other comparison websites which link-out the customer when they want to buy a product, CHECK24 offers integrated ways of effecting a contract. The comparison services for prices and product features are free of charge for the customer. Furthermore, customers get free independent advice by phone from qualified product experts.

Wheelhouse CMS is one of Germany`s leading price comparison websites. On CHECK24.de customers can compare a wide range of products from the fields of insurance, money, energy, telecommunications, and travel and thus save hundreds of Euros per year. In contrast to most other comparison websites which link-out the customer when they want to buy a product, CHECK24 offers integrated ways of effecting a contract. The comparison services for prices and product features are free of charge for the customer. Furthermore, customers get free independent advice by phone from qualified product experts.

CHECK24 is one of Germany`s leading price comparison websites. On CHECK24.de customers can compare a wide range of products from the fields of insurance, money, energy, telecommunications, and travel and thus save hundreds of Euros per year. In contrast to most other comparison websites which link-out the customer when they want to buy a product, CHECK24 offers integrated ways of effecting a contract. The comparison services for prices and product features are free of charge for the customer. Furthermore, customers get free independent advice by phone from qualified product experts.
Qwk.io is the quickest, easiest way to conduct surveys. It's built on Ruby on Rails and MongoDB for the backend.

CyberAgent, Inc. has strongly expanded its business into a wide range of internet services. Currently, CyberAgent's major business categories are Internet Media, Internet Advertising Agency and the Investment Development. CyberAgent, Inc. is using MongoDB in "Ameba" services. We also have an American office: CyberAgent America.

Social Game with node.js + MongoDB Presentation from Mongo Tokyo (March 2011) provides web and mobile services that motivate people to move more, share activities with friends, and cheer others – bringing a fun and social dimension into physical activity and wellbeing. Users can choose from over 350 activities and the workouts can be shared also on Facebook and Twitter. HeiaHeia.com’s technology offers a cost-efficient, commercially attractive way for various communities to provide engaging, customized online services for wellbeing.

NewsCurve is an analytics tool providing effectiveness metrics of online content in real-time. We use MongoDB as primary database storage to store analytics data.

Accounting SaaS Japan provides Accounting Services via SaaS targeted towards Japanese certified accountants and small and mid-size businesses. By using MongoDB in our tax return service (other services include, but are not limited to, general ledger and payroll), we are able to achieve the flexibility necessary to meet the rapidly changing demands and specifications vital for such a system—something that is difficult to accomplish with the relational or file-based approach.

Fabric Structures Community is a project to ensure the enlargement of the textile structures market share in the overall construction sector by providing more comprehensive and up-to-date information to potential customers about the textile structures range and opportunities, as well as to companies operating in this field. MongoDB is used for storing and indexing our member profiles and company directory.

Brenden Digital uses MongoDB for everything except transactional features, and even those are being migrated. We appreciate MDB for its smaller size, much fast performance and ease of implementation. It repeatedly exhibits an elegance, a sublime aura that is the mark of excellence and thorough comprehension.

Attachments.me is a search engine for your email attachments. MongoDB stores all the meta-information surrounding attachments, messages, and users.

Thumbtack is an online marketplace for local services. We use MongoDB as the datastore for all of our analytics, due to its excellent performance, flexible document format and powerful query language. More details can be found in our recent blog post: Building our own tracking engine with MongoDB.

ChirpAt.Me enables Twitter users to build their own real-time discussion board to share their passions and expertise with their friends and followers. ChirpAt.Me uses MongoDB for all of their data storage from user sessions to messages and preferences.
| **DianPing.com** | DianPing.com is a leading city life guide site and local businesses promotion platform in China, it provides objective and rich local information, in the areas of restaurants, entertainment, shopping, beauty, weddings and various other categories. MongoDB is used for: user-behavior analysis system the counter on businesses, users, groups simple message queue service. |
| **Venmo** | Venmo is a free and easy to use mobile app friends can use to pay each other back for lunch, dinner, drinks, rent, groceries, tickets, and trips. Venmo uses MongoDB for internal reporting and for storing activities published by users for their friends to browse. |
| **Intelie** | Intelie is a software that receives data from several sources and, using Complex Event Processing (CEP) and machine learning techniques, makes it possible to detect anomalies and known problems on data centers in real time. We use MongoDB to store all the data that IEM analyses over time, about 5000 documents per minute for one company. Storing these events allow us to 'replay' past scenarios to test new rules, in addition to providing dashboards and charts of historical data. |
| **SIGNAL** | First, we are using MongoDB's geospatial queries to power location based marketing campaigns. Our users can create a SMS marketing campaign to ask users for their zip code in reply to an SMS message, perform a lookup of known locations (stores) based on that zip code, and return the nearest location to the user. Second, we are using MongoDB to hold a set of summary documents to help us calculate a series of statistics for our Email and SMS subscription lists. Instead of gathering these statistics by running SQL queries in tables with anywhere from 30 - 100 million rows, we're able to get the same numbers by looking at anywhere from 30 - 365 summary documents. As you can imagine, this dramatically speeds up these queries. This use case is documented at [http://johnpwood.net/2011/05/31/fast-queries-on-large-datasets-using-mongodb-and-summary-documents/](http://johnpwood.net/2011/05/31/fast-queries-on-large-datasets-using-mongodb-and-summary-documents/). |
| **Directdialogs.com** | Directdialogs.com is a cloud-based direct marketing application with email/mobile campaign management capability and a flexible no-card loyalty program. MongoDB works along with Sql Azure and serves as a powerful cache with analytical capabilities. Segmentation of customer/transaction data for marketing purposes, OLAP reporting/analytics based on customer purchase data and data mining models run on MongoDB. |
| **DC Storm** | DC Storm helps marketers increase sales, deliver higher ROI and target their digital marketing spend better. The intuitive technology platform and first class service provide actionable insight and control across all digital channels; ensuring clients have the competitive edge to succeed online. MongoDB powers the Storm Platform's dashboard and template storage technology, allowing for easy scalability and redundancy. |
| **Bouncely** | Bouncely uses MongoDB to save details of every bounced message from Amazon SES. We parse everything and store thousands of records per day on MongoDB. It is also used to retrieve all the information and run MapReduce in order to present statistics to users. |
| **PCClicks** | PCClicks uses MongoDB to help customers easily connect with local service providers of any kind. Thousands of people have found and booked everything from plumbers, maids, and gardeners, to scuba instructors in Mexico and hot air balloon rides in California. |
| **Magnetic** | Magnetic is the leader in search retargeting, enabling advertisers and publishers to use search to reach their most relevant audience online. Magnetic uses MongoDB on servers processing billions of events a month. Beyond performance and scalability, Mongo is a key enabling technology for Magnetic. We leverage the rich data model and storage and analytics features to deliver real-time analytics and simplify and unify a mix of high-performance, web application and data processing servers. MongoDB gives Magnetic a competitive advantage. |
| **Okezone.com** | Okezone.com is the leader in search retargeting, enabling advertisers and publishers to use search to reach their most relevant audience online. Magnetic uses MongoDB on servers processing billions of events a month. Beyond performance and scalability, Mongo is a key enabling technology for Magnetic. We leverage the rich data model and storage and analytics features to deliver real-time analytics and simplify and unify a mix of high-performance, web application and data processing servers. MongoDB gives Magnetic a competitive advantage. |
| **OpenChime** | OpenChime uses MongoDB to help customers easily connect with local service providers of any kind. Thousands of people have found and booked everything from plumbers, maids, and gardeners, to scuba instructors in Mexico and hot air balloon rides in California. |
is a behavioral targeting platform that delivers real-time personalization to existing websites.

**Monoloop**

MongoDB is the core datastore that delivers the speed needed to build visitor profiles, compute scores, and deliver personalized content to the visitor. The service is currently in open Beta.

**Yeay.me**

is a small startup that uses Grails and MongoDB for building a product recommendation service.

**Yeay.me**

MongoDB is used for all its stored data.

**Activesphere**

provides services using rails and MongoDB. We use MongoDB for our internal applications as well.

**SocialCityDeals**

uses MongoDB to store rapidly changing daily deals related data. Every deal has its own set of fields and new fields keep showing up frequently making it hard to come up with a correct DB architecture to store the data. With MongoDB's capabilities, we were able to reduce our development effort in half for the site.

**Thin PHP Framework**

is a lightweight, flexible open source PHP5 MVC framework. It aims to be a fast, simple, scalable and highly extensible framework. MongoDB is used as a module in TPF to help users scale their database easily.

**Newsman App**

is an email service provider which focuses on speed and high deliverability. We use MongoDB for now to build our powerful subscribers segmentation tool. We allow multiple variables to be stored for each subscriber thus MongoDB schema-free was the perfect choice. We plan to switch to MongoDB for all our other database operations in the future.

**Sizzix**

uses MongoDB to power its e-commerce website that sells thousands of products online.

**Gazaro**

uses MongoDB as the backend for our business-to-business side, storing tens of millions of raw products across a range of companies.

**Dropzone.by**

uses MongoDB for storing content, banners, taglines and other information. We have also introduced OAuth 2.0 and implemented it using Python/Twisted/MongodB tandem.

**Cairenhui**

is a Financial Community. The web application is coded in Java (using morphia ORM framework) and uses Mongodb_1.8.1 (based on auto-sharding) to store all UGC data.

**Ez Texting**

uses MongoDB to queue incoming text messages before our application processes them and outgoing text messages after our application processes them for delivery.

**iKeepm**

is a cloud-based home inventory application. iKeepm uses MongoDB to store photos and file uploads in GridFS.
Maansu.com sells 16 Million books.

www.motores24h.pt uses MongoDB for its data storage needs.

Techunits uses MongoDB for its data storage needs. Techunits is a modular platform that can cater for any type of adverts.

Buzzers.co.za uses MongoDB for its performance, scalability, sharding, and NoSQL requirements.

Buzzers.co.za uses MongoLantern for full-text search for products and related entities.

Paraimpu is a social networking platform for the Web of Things. MongoDB is used for all the persistent data storage requirements.

Trivian uses MongoDB to store quiz questions and places.

Business.com uses MongoDB to power its CMS and taxonomy systems.

General Flows is building an app where users can create databases of their stuff, then plug them into pre-baked 'flows' to let them do useful things with their stuff. They used MongoDB because it could handle totally unknown data structures.

Art.sy uses MongoDB to store art collections.

Spoondate is a social community that connects people through shared experiences. MongoDB powers Spoondate's geolocation services, analytics, and member search.

uQuery Inc. uses MongoDB to process 30GB of data per day.
46elks uses MongoDB for the backend of its cloud communication platform. By using MongoDB we can make sure the data of our SMS and phone calling customers is kept safe and always accessible.

Chalkboard is a daily marketing solution for small businesses to communicate instantly, locally and socially over mobile and web. Chalkboard works with thousands of local businesses and reaches millions of consumers across third party mobile applications, websites and navigation systems. We utilize MongoDB to archive the 100 millions of analytics data records where we can easily analyze the data internally. With the growing usage of Chalkboard, MongoDB allows to scale our infrastructure in the near future.

tisProperty is a Real realestates listed on to store our crawling

Digital Media Exchange uses MongoDB for several things actually, and we’ve been using it more and more instead of our main postgres db. The following are some of our use cases: 1. Search engine index storage 2. We run a lot of promo’s for our products so we store promo data in mongo. Love the schema-less design. 3. We use it as replacement for our table views to store denormalized data These are just some of the use cases, and I’m very confident that we will find more uses for MongoDB.

Daily Gourmet provides regular offers on artisanal and gourmet food products. “We’re using MongoDB for our extensive logging/analytics. MongoDB’s performance has enabled us to capture information that just wasn’t possible with MySQL.”

Singly, a sponsored by Singly over their personal d as a personal data s

Loc. cit. is a small new idea in publishing. Translate-as-you-go, a paragraph at a time. A sentence alone can be explosive. Translate polemically: every passage can be retranslated. MongoDB is our backend database for everything. It allows us to carry thousands of paragraphs from public domain books. We use Mongoengine for Django authentication functionality.

THE LOCKER PROJECT

Loc-cit

Naver Japan utilizes recently released photo sharing iPhone app, “NAVER Photo Album ((http://itunes.apple.com/jp/app/id449576650 with MongoDB (Japanese) - Presentation at Tokyo’s MongoDB study group (September 2011) http://www.slideshare.net/naverjapan/mongodb-9422893

My eStore App uses content via Mongo.

<thead>
<tr>
<th>Company</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CloudAmp</td>
<td>is a data platform for developers. We give you an instant backend for your apps, combining as many data sources as you want. CloudAmp uses MongoDB as storage for data that are aggregated across different private and public data sources and APIs to solve the problem of cloud-scale, real-time data integration for app developers. We also provide a Node.js library &quot;connector&quot; to push data up to our platform from private data sources like MongoDB, MySQL, Redis and public sources like Facebook and Twitter, where we organize it along with other data streams.</td>
</tr>
<tr>
<td>Piyavate International Hospital</td>
<td>is a leader in international hospital in Thailand and South East Asia. Their new website need some major enhancement that fit with our ColdFusion and MongoDB, also full text search with Solr. Multi-languages, complex structure and relationship, document management, WYSIWYG form creation, tag system, intranet built-in, full text search, digital asset management. All of these features are totally depend on MongoDB. Almost impossible or very difficult to approach via RDBMS way. That's why MongoDB rules!</td>
</tr>
<tr>
<td>Mindvalley</td>
<td>is using MongoDB for our in-house analytics, using Sinatra, async_sinatra, Rails, and Mongoid. The ability to &quot;fire-and-forget&quot; helps us capture and collect site data without compromising page speed, while its document-centric features allows us to quickly retrieve all information about a particular lead. Due to our successful pilot, we're planning to use MongoDB for storing affiliate data, an in-house developed CMS, as well as the social graph in a community application.</td>
</tr>
<tr>
<td>Cookfollower</td>
<td>is a Twitter like micro blogging, social cooking website where you can find great recipes and meet new people. MongoDB is used to store all recipe data and user's social graph.</td>
</tr>
<tr>
<td>Weconext</td>
<td>develops and sales a secured web platform to allow professionals to work closer with their partners. This innovative platform allows simple collaborations, concrete work on the same data and quick exchanges of information. MongoDB stores for Weconext all the dynamic part of its backend.</td>
</tr>
<tr>
<td>Visual.ly</td>
<td>is building the Data Visualization platform for Big Data. Visual.ly is using MongoDB for the main data store for their core product. Provides the key to managing, understanding, engaging, and activating real-time user experiences for media and brands. We use MongoDB to store terabytes of statistical data and content that feed our curation, charting and analytics products.</td>
</tr>
<tr>
<td>Trendrr</td>
<td>is an online community with over 3 million users world-wide. Everyday over 1.5 million messages are exchanged by our users and we rely exclusively on MongoDB for all our database needs.</td>
</tr>
<tr>
<td>Wireclub</td>
<td>creates addictive social games. Our games have a loyal fan base encompassing millions of worldwide players across multiple social networks like Facebook, Myspace and Hi5. MongoDB is used as the primary data store for game data as well as our analytics platform.</td>

<tr>
<td>---------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CMI Soft</td>
<td>Uses MongoDB to run the backend of all their custom (Ruby on Rails based) CMS driven websites. They have also developed intranets, social networking apps and two community-oriented e-commerce concepts using Rails with MongoDB.</td>
</tr>
<tr>
<td>fyndlr</td>
<td>Implements MongoDB from the backend service that powers fyndlr. All data about lost &amp; found posts and users are organized in MongoDB collections. They rely heavily on MongoDB for geolocation functionality. Since their service was written in Python, they implemented PyMongo to interface with their MongoDB instance.</td>
</tr>
<tr>
<td>Exceptiontail</td>
<td>Uses MongoDB in order to store user and exception information. Exceptiontail is a .Net exception management service that allows developers to know when their applications crashed and lets them see the entire system/process/exception information for that crash.</td>
</tr>
<tr>
<td>AdHui</td>
<td>Uses MongoDB for real-time cookie analytics. Leading provider for DSP and SEM optimization.</td>
</tr>
<tr>
<td>Travelmap</td>
<td>Uses MongoDB to store hotels, tickets, and holiday packages aggregated live from a bunch of sources. Travelmap is one of the biggest travel websites in the Netherlands. MongoDB proved to be up to 5 times faster and much more scalable than their previous MySQL installation, on the same hardware! On average, their database contains ~20 million objects.</td>
</tr>
<tr>
<td>Global Advertisers</td>
<td>Uses MongoDB to help with blogging. Global is India’s most progressive outdoor advertising agency. Armed with Mumbai’s largest hoarding @ Bandra to widest hoarding @ Airport. Global is one stop for anything and everything under OOH.</td>
</tr>
<tr>
<td>Melt DSP</td>
<td>Is using MongoDB to answer millions of bid requests per hour in a time shorter than 5ms each!</td>
</tr>
<tr>
<td>Startup Threads Monthly</td>
<td>Uses MongoDB as its backend database for customer information.</td>
</tr>
<tr>
<td>Songza</td>
<td>Uses MongoDB to hold all the data that drives the website. Songza is a Music Concierge - a free streaming service that finds you the right playlist at the right time. Users, playlists, interaction history, etc. The schema-free design is a big win for them. When they used MySQL, schema migrations were a major pain, and occasionally a cause of extended downtime.</td>
</tr>
</tbody>
</table>
Ciris is a new application where you can find contact information about the people in Costa Rica. We use MongoDB to store the documents for every person and registered business in the country.

Socialbakers Inc. uses MongoDB to store great amount of statistical data from social networks.

Neon Grid uses MongoDB to store profiles, and associate creative skills with our users.

Ex Machina develops second screen applications for large TV shows around the world. This typically involves tens or hundreds of thousands of people interacting with our clusters at exactly the same time and as a result we needed a storage solution that offers very good performance, is easy to scale up fast and remains cost-efficient regardless of scale. We never looked back.

BellyBallot is a new site for expecting parents that mixes social media with baby names. BellyBallot uses MongoDB for its primary content serving which includes the thousands of names around the world, and their associated meanings, pronunciations, etc. BellyBallot’s custom content management system (built on Rails) is also on MongoDB.

AdMaster uses MongoDB for its social networking analytics product, WeiboMaster, to store the information of over 40,000,000 followers and 700,000 tweets with 35,000,000 relevant comments and retweets.

GetVega is a second memory for your projects and passions. GetVega helps you collect in a really smart way the relevant data from the webpage you visit: pictures, videos, prices... Everything goes then in a collaborative list on GetVega where each will be able to comment, rate and compare everything you collected. GetVega.com uses MongoDB for the whole back-end (except search with Solr), after a first prototype with MySQL. MongoDB allows us to store versatile data in a blazing fast scalable way!

5Searches uses MongoDB to manage all of my social media users and profiles!

barbull.co.uk uses MongoDB to store a list of searchable attributes for personal trainers, which is fast and reliable and the ability to add custom functions and map reduce means that our complex distance calculations are a breeze.
Power-lan uses MongoDB to store real-time data from IP sensors connected to the internet (over 3G). Main applications are:

- Nondestructive testing (Highway, Aeolian, ...)
- Automation and Smart Grid applications

Sidebuy is a product deal aggregator that crawls the web and uses an intelligent system to automatically find products and deals. The challenge with traditional DBMS was to store entities with different properties. With MongoDB, entities are stored as documents. Also, with MongoDB, expansion problems across our servers have been solved. Sidebuy crawls thousands of webpages per day and stores everything in BSON documents now. Geospatial querying is also a big plus for Sidebuy.com.

OviPets uses MongoDB for everything in their new Facebook game OviPets (http://ovipets.com), and are very happy with the performance and simplicity of MongoDB. They are growing rapidly, and MongoDB is scaling beautifully with them. Apart from various game-related collections, they also use MongoDB for session storage and image caches.

Tip or Skip uses MongoDB for all of their database needs, including user and product storage, interaction, analytics, and job queues.

Nodegrid provides a hosting platform for MongoDB and also uses MongoDB as the back-end for its Nodegrid service.

Courseoff uses MongoDB to store student-created schedules as well as the schedule listings themselves.

ClaimAble operates a web app for insurance claims management. MongoDB is their primary datastore. They use it exclusively to power their platform and API.
Ponder Design uses MongoDB to power all custom webapps we write for our customers. From a ticket portal for a large student event to CMS systems to custom surveys. Mongo lets us be very flexible in implementing new features or adjusting existing ones as we discover our customers real requirements and wishes.

Stamped is a recommendation-based social network application that allows users to advocate for their favorite places and things. MongoDB is used to store and receive user data and are responsible for coordinating the creation and enrichment of data about stampable entities.

The Engineering Behind the Stamped Backed

Hopper uses MongoDB for storage of all of our user data and content.

Hopper

Recommendly INC

AlisverisRobotu.com

AlisverisRobotu.com uses MongoDB for many things, including inventory management and transaction logging.

ITERNOVA SL

ITERNOVA SL proudly uses MongoDB in our Intelligent Transport Systems (ITS) management system, to store real-time data obtained from devices installed in roads (weather stations, mesh and sensorial networks...), and veh...

tvb.com

tvb.com uses MongoDB for storage meta-data of programme in mytv with different data-type. Since MongoDB is schema free it fits our needs. We also use MongoDB in real-time analytics with map-reduce processing. We create statistics for site traffic and a real-time programme chart.
Ob1b.com is one of China's price compare websites of 3C products. On ob1b.com, customers can compare prices and find product information from E-Business websites in China, and customers can find the right products they want to buy.

We use MongoDB as our data store engine. We have chosen MongoDB due to its simplicity, ease of study, and faster performance compared to traditional databases.

Talis uses MongoDB to store and serve the graph-based data model in its Community Edition product (http://community.talisaspire.com). By using MongoDB as a replacement for the existing database, we achieved an order of magnitude better performance. At the same time, converting to MongoDB allowed us to simplify our stack by removing complex caching infrastructure external to our old database.

Digital Flow uses MongoDB as the database of choice for our clients' deployments. The sheer scalability, ease of use, and deployment are a no-brainer for us.

Transmachina uses MongoDB as the database of choice for our clients' deployments. The database handles huge amounts of linguistic data (such as aligned sentences with loads of custom indexing) which is used for automated language learning and delivering our website translation service, Sprawk.

About.me is currently processing millions of messages per day. After outgrowing an existing MQ solution, About.me turned to MongoDB. An old MQ cluster was replaced with a sharded Mongo deployment. In addition to the sharding ability, MongoDB provided options that allowed About.me to tailor durability to the level required.

Dealer.com deployed a site configuration management system based on MongoDB. The current system supports configuration files for over 15,000 customer sites with thousands of revisions per site and an on-disk size of almost 200GB.

**Notes:**
- Review19 uses MongoDB as a complete solution for its scalable distributed Massive Multiplayer Online Gaming Engine, born from Zynga's original Mafia Wars game in 2008.
- iQmetrix uses MongoDB for its product catalog and configuration tool for XQ, an interactive, customer-facing solution for the wireless retail industry. They are running a MongoDB replica set in Microsoft's cloud platform Windows Azure.
- Documents Software S.L. uses MongoDB to hold all tracking information in a highly available and scalable sharded replica set. MongoDB provides them with the speed and scalability needed to store and process all document reading information they gather from document recipients, producing insight on readers' behavior and real-time notifications to users.
- JackThreads, an ecommerce company, uses MongoDB for inventory tracking and reporting, allowing them to track products down to the individual unit.
- Shelf9 combines MongoDB as storage for their real-time data-mining code.
- Luminis Technologies uses MongoDB to build the Leren-op-Maat system, an e-learning platform focused on personalized learning for high schools in the Netherlands. They are currently working with several high schools and face the challenge of managing extra load with flexible scaling.
- Betterez is a SaaS platform designed to improve both past and present configuration spanning the main data store and analytics data store. MongoDB is used extensively in a replica set configuration spanning multiple data centers, driving the Node.js web application and housing both main and analytics data stores.
- DUVRI 81.08 is a governmental web application to help Italian corporates manage workspace safety risks to prevent accidents and protect workers' lives. The application is built in PHP with Zend Framework and uses MongoDB as the documental database wrapped by Doctrine ODM.
- Zomby is a massively multiplayer, location-based zombie apocalypse game developed by Kudzu Creative Group. They chose MongoDB for scalability, as their user-base expands globally, they will need multiple servers around the world. MongoDB and Erlang will allow them to handle this efficiently.
- Gusanito.com uses MongoDB for their Facebook Apps.
Aion Innovations uses MongoDB as the database for the whole application.

Support.com, Inc provides technology services and software for consumers and small business. They use MongoDB to store massive data sets related to automated snapshots of state and error information for computers, devices and networks. They analyze this data in real-time to identify potential root causes and outcomes of home technology issues, make relevant product recommendations and predict patterns that may lead to subscriber churn.

Footballrrating uses MongoDB to store all user data, such as login information, connecting to social network, match votes, and player tracking configurations. Their schema-less design means great flexibility in pushing new features without having to migrate clunky SQL tables around multiple servers.

Factile is an online free survey platform based on the flexible structure that MongoDB provides. Each survey is different in structure. Factile uses MongoDB for its fast performance a survey tool need and we run analytics on the survey responses easily.

Dir uses MongoDB to store all of its data models and finds it very useful for creating embed documents. Dir is a simple business management tool.

Socialbakers uses MongoDB for its API. The company has developed an application that makes it easy for to get sophisticated metrics on performance through Facebook.

YMIRLINK is a Tokyo based e-mail service provider specializing in mass e-mail sending service for email marketing. In March 2012 we sent a record 1.6 billion e-mail messages per month via our SaaS-based mail system. In July 2012, we further improved the performances of our e-mail sending service by using MongoDB as our new mail transfer agent.

SSD
We are not experts on solid state drives, but tried to provide some information here that would be helpful. Comments very welcome.

- Write Endurance
  - Reserve some unpartitioned space
  - smartctl
- Speed
- Reliability
- Random reads vs. random writes
- PCI vs. SATA
- RAM vs. SSD
- FlashCache
- OS scheduler
- Run mongoperf
- Helpful links

Multiple MongoDB users have reported good success running MongoDB databases on solid state drives.

**Write Endurance**

Write endurance with solid state drives vary. SLC drives have higher endurance but newer generation MLC (and eMLC) drives are getting better.

As an example, the MLC Intel 320 drives specify endurance of 20GB/day of writes for five years. If you are doing small or medium size random reads and writes this is sufficient. The Intel 710 series is the enterprise-class models and have higher endurance.

If you intend to write a full drive's worth of data writing per day (and every day for a long time), this level of endurance would be insufficient. For large sequential operations (for example very large map/reduces), one could write far more than 20GB/day. Traditional hard drives are quite good at sequential I/O and thus may be better for that use case.

- Blog post on SSD lifespan

**Reserve some unpartitioned space**

Some users report good results when leaving 20% of their drives completely unpartitioned. In this situation the drive knows it can use that space as working space. Note formatted but empty space may or may not be available to the drive depending on TRIM support which is often lacking.

**smartctl**

On some devices, "smartctl -A" will show you the Media_Wearout_Indicator.

```bash
$ sudo smartctl -A /dev/sda | grep Wearout
233 Media_Wearout_Indicator 0x0032   099   099   000    Old_age   Always       -       0
```

**Speed**

A paper in ACM Transactions on Storage (Sep2010) listed the following results for measured 4KB peak random direct IO for some popular devices:

<table>
<thead>
<tr>
<th>Device</th>
<th>Read IOPS</th>
<th>Write IOPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intel X25-E</td>
<td>33,400</td>
<td>3,120</td>
</tr>
<tr>
<td>FusionIO ioDrive</td>
<td>98,800</td>
<td>75,100</td>
</tr>
</tbody>
</table>

Intel's larger drives seem to have higher write IOPS than the smaller ones (up to 23,000 claimed for the 320 series). More info here.

Real-world results should be lower, but the numbers are still impressive.

**Reliability**

Some manufacturers specify reliability stats indicating failure rates of approximately 0.6% per year. This is better than traditional drives (2% per year failure rate or higher), but still quite high and thus mirroring will be important. (And of course manufacture specs could be optimistic.)

**Random reads vs. random writes**

Random access I/O is the sweet spot for SSD. Historically random reads on SSD drives have been much faster than random writes. That said,
random writes are still an order of magnitude faster than spinning disks.

Recently new drives have released that have much higher random write performance. For example the Intel 320 series, particular the larger capacity drives, has much higher random write performance than the older Intel X25 series drives.

**PCI vs. SATA**

SSD is available both as PCI cards and SATA drives. PCI is oriented towards the high end of products on the market.

Some SATA SSD drives now support 6Gbps sata transfer rates, yet at the time of this writing many controllers shipped with servers are 3Gbps. For random IO oriented applications this is likely sufficient, but worth considering regardless.

**RAM vs. SSD**

Even though SSDs are fast, RAM is still faster. Thus for the highest performance possible, having enough RAM to contain the working set of data from the database is optimal. However, it is common to have a request rate that is easily met by the speed of random IO's with SSDs, and SSD cost per byte is lower than RAM (and persistent too).

A system with less RAM and SSDs will likely outperform a system with more RAM and spinning disks. For example a system with SSD drives and 64GB RAM will often outperform a system with 128GB RAM and spinning disks. (Results will vary by use case of course.)

One helpful characteristic of SSDs is they can facilitate fast “preheat” of RAM on a hardware restart. On a restart a system's RAM file system cache must be repopulated. On a box with 64GB RAM or more, this can take a considerable amount of time – for example six minutes at 100MB/sec, and much longer when the requests are random IO to spinning disks.

**FlashCache**

FlashCache is a write back block cache for Linux. It was created by Facebook. Installation is a bit of work as you have to build and install a kernel module. Sep2011: If you use this please report results in the mongo forum as it's new and everyone will be curious how well it works.

**OS scheduler**

One user reports good results with the noop IO scheduler under certain configurations of their system. As always caution is recommended on nonstandard configurations as such configurations never get as much testing...

**Run mongoperf**

mongoperf is a disk performance stress utility. It is not part of the mongo database, simply a disk exercising program. We recommend testing your SSD setup with mongoperf. Note that the random writes it are a worst case scenario, and in many cases MongoDB can do writes that are much larger.

**Admin UIs**

MongoDB does not include a GUI-style administrative interface. Instead most administration is done from command line tools such as the mongo shell. However some UI's are available as separate community projects and are listed below. Some are focused on administration, while some focus on data viewing.

See also:

- The Mongo Monitoring Service (MMS) from 10gen.
- Tim Gourley's blog has a good summary of the tools.
- The built-in replica set admin UI page.

**Tools**

- Tools
  - Edda
  - Fang of Mongo
  - UMongo (formerly JMongoBrowser)
• MongoExplorer

Fang of Mongo

- http://blueone.pl:8001/fangofmongo/
- http://github.com/Fiedzia/Fang-of-Mongo

A web-based user interface for MongoDB build with django and jquery.
It will allow you to explore content of mongodb with simple but (hopefully) pleasant user interface.

Features:

- field name autocompletion in query builder
- data loading indicator
- human friendly collection stats
- disabling collection windows when there is no collection selected
- twitter stream plugin
- many more minor usability fixes
- works well on recent chrome and firefox

To track progress on twitter: @fangofmongo

UMongo (formerly JMongoBrowser)

- home page: http://edgytech.com/umongo/
- github: http://github.com/agirbal/umongo
- download: https://github.com/agirbal/umongo/downloads

UMongo is a GUI app that can browse and administer a MongoDB cluster. It is available for Linux, Windows and Mac OSX.

MongoExplorer

- http://mongoexplorer.com/

MongoExplorer is a MongoDB management tool, written in Silverlight (.net – works in windows/osx/?linux?).

Features:

- Easy to use
- Shows all the collections and documents of the database
- Uses a convenient tree view for documents
- Drag’n’drop is fully supported
- Document in-place editing
MongoHub

MongoHub is a native OS X GUI.

MongoVision

- [http://code.google.com/p/mongo-vision/](http://code.google.com/p/mongo-vision/)

MongoVision is a MongoDB management tool, written for Prudence.

Features:
- Extended JSON support
- Tabular view
- Click to sort
- Filter boxes to alter query
- Auto-refresh
MongoVUE

- http://blog.mongovue.com

MongoVUE is a .NET GUI for MongoDB.

mViewer

- http://imaginea.com/mviewer

mViewer is a web-based MongoDB administration tool.

Opricot

Opricot is a hybrid GUI/CLI/Scripting web frontend implemented in PHP to manage your MongoDB servers and databases. Use as a point-and-click adventure for basic tasks, utilize scripting for automated processing or repetitive things.

Opricot combines the following components to create a fully featured administration tool:

- An interactive console that allows you to either work with the database through the UI, or by using custom Javascript.
- A set of simple commands that wrap the Javascript driver, and provide an easy way to complete the most common tasks.
- Javascript driver for Mongo that works on the browser and talks with the AJAX interface.
- Simple server-side AJAX interface for communicating with the MongoDB server (currently available for PHP).
PHPMoAdmin

- http://www.phpmoadmin.com/

**PHPMoAdmin** is a MongoDB administration tool for PHP built on a stripped-down version of the Vork high-performance framework.

- Nothing to configure - place the moadmin.php file anywhere on your web site and it just works!
- Fast AJAX-based XHTML 1.1 interface operates consistently in every browser!
- Self-contained in a single 95kb file!
- Works on any version of PHP5 with the MongoDB NoSQL database installed & running.
- Super flexible - search for exact-text, text with * wildcards, regex or JSON (with Mongo-operators enabled)
- Option to enable password-protection for one or more users; to activate protection, just add the username-password(s) to the array at the top of the file.
- **E_STRICT** PHP code is formatted to the Zend Framework coding standards + fully-documented in the phpDocumentor DocBlock standard.
- Textareas can be resized by dragging/stretching the lower-right corner.
- Free & open-source! Release under the GPLv3 FOSS license!
- Option to query MongoDB using JSON or PHP-array syntax
- Multiple design themes to choose from
- Instructional error messages - phpMoAdmin can be used as a PHP-Mongo connection debugging tool

PHPMoAdmin can help you discover the source of connection issues between PHP and Mongo. Download **phpMoAdmin**, place the moadmin.php file in your web site document directory and navigate to it in a browser. One of two things will happen:

- You will see an error message explaining why PHP and Mongo cannot connect and what you need to do to fix it
- You will see a bunch of Mongo-related options, including a selection of databases (by default, the "admin" and "local" databases always exist) - if this is the case your installation was successful and your problem is within the PHP code that you are using to access MongoDB, troubleshoot that from the [Mongo docs on php.net](http://www.phpmoadmin.com/)

![PHPMoAdmin](http://www.phpmoadmin.com/)

RockMongo

**RockMongo** is a MongoDB management tool, written in PHP 5.

Main features:

- easy to install, and open source
- multiple hosts, and multiple administrators for one host
- password protection
- query dbs
- advanced collection query tool
- read, insert, update, duplicate and remove single row
- query, create and drop indexes
- clear collection
• remove and change (only work in higher php_mongo version) criteria matched rows
• view collection statistics

Genghis
A single-file MongoDB admin app, which is available as either a Ruby or PHP script: http://genghisapp.com/

Mecclipse
Eclipse plugin for mongodb: http://update.exoanalytic.com/org.mongodb.mecclipse/

Humongous
A standalone MongoDB browser built in Ruby: http://github.bagwanpankaj.com/humongous/

MongoDB ODA plugin for BIRT
The MongoDB ODA plugin for BIRT is an Eclipse based plugin which enables you to connect to a Mongo database and pull out data to display in your BIRT report. The interface is simple and an extensive user guide is also provided with the release.
http://code.google.com/a/eclipselabs.org/p/mongodb-oda-birt-plugin/

Monad Management for MongoDB
An operations and administration management tool for MongoDB, with dashboards, alerting, and monitoring graphs.
Visit their website for a demo.

Commercial

Database Master
Database Master from Nucleon Software.
Seems to be written in .net for windows (windows installer).
Features:
• Tree view for dbs and collections
- Create/Drop indexes
- Server/DB stats
- Support RDBMS (MySQL, postgres, ...)

**Data Viewers**

mongs

- [http://www.whit537.org/mongs/](http://www.whit537.org/mongs/)

**REST Interfaces**

DrowsyDromedary (Ruby)

DrowsyDromedary is a REST layer for Mongo based on Ruby.

MongoDB Rest (Node.js)

MongoDB Rest is an alpha REST interface to MongoDB, which uses the MongoDB Node Native driver.

Mongoddb Java REST server

Mongoddb Java REST server based on Jetty.

**HTTP Interfaces**

Sleepy Mongoose (Python)

Sleepy Mongoose is a full featured HTTP interface for MongoDB.

**HTTP Console**

MongoDB provides a simple http interface listing information of interest to administrators. This interface may be accessed at the port with numeric value 1000 more than the configured mongod port; the default port for the http interface is 28017. To access the http interface an administrator may, for example, point a browser to [http://localhost:28017](http://localhost:28017) if mongod is running with the default port on the local machine.
Here is a description of the informational elements of the http interface:

<table>
<thead>
<tr>
<th>element</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>db version</td>
<td>database version information</td>
</tr>
<tr>
<td>git hash</td>
<td>database version developer tag</td>
</tr>
<tr>
<td>sys info</td>
<td>mongod compilation environment</td>
</tr>
<tr>
<td>dblocked</td>
<td>indicates whether the primary mongod mutex is held</td>
</tr>
<tr>
<td>uptime</td>
<td>time since this mongod instance was started</td>
</tr>
<tr>
<td>assertions</td>
<td>any software assertions that have been raised by this mongod instance</td>
</tr>
<tr>
<td>replInfo</td>
<td>information about replication configuration</td>
</tr>
<tr>
<td>currentOp</td>
<td>most recent client request</td>
</tr>
<tr>
<td># databases</td>
<td>number of databases that have been accessed by this mongod instance</td>
</tr>
<tr>
<td>curclient</td>
<td>last database accessed by this mongod instance</td>
</tr>
<tr>
<td>Cursors</td>
<td>describes outstanding client cursors</td>
</tr>
<tr>
<td>master</td>
<td>whether this mongod instance has been designated a master</td>
</tr>
<tr>
<td>slave</td>
<td>whether this mongod instance has been designated a slave</td>
</tr>
<tr>
<td>initialSyncCompleted</td>
<td>whether this slave or repl pair node has completed an initial clone of the mongod instance it is replicating</td>
</tr>
<tr>
<td>DBTOP</td>
<td>Displays the total time the mongod instance has devoted to each listed collection, as well as the percentage of available time devoted to each listed collection recently and the number of reads, writes, and total calls made recently</td>
</tr>
<tr>
<td>dt</td>
<td>Timing information about the primary mongod mutex</td>
</tr>
</tbody>
</table>

**HTTP Console Security**

If security is configured for a mongod instance, authentication is required for a client to access the http interface from another machine.
Simple REST Interface

The mongod process includes a simple REST interface, with no support for insert/update/remove operations, as a convenience – it is generally used for monitoring/alerting scripts or administrative tasks. For full REST capabilities we recommend using an external tool such as Sleepy.Mongoose.

**v1.4+:** This interface is disabled by default. Use --rest on the command line to enable.

To get the contents of a collection (note the trailing slash):

```http
http://127.0.0.1:28017/databaseName/collectionName/
```

To add a limit:

```http
http://127.0.0.1:28017/databaseName/collectionName/?limit=-10
```

To skip:

```http
http://127.0.0.1:28017/databaseName/collectionName/?skip=5
```

To query for `{a : 1}`:

```http
http://127.0.0.1:28017/databaseName/collectionName/?filter_a=1
```

Separate conditions with an `&`:

```http
http://127.0.0.1:28017/databaseName/collectionName/?filter_a=1&limit=-10
```

Same as `db.$cmd.findOne({'listDatabase':1})` on the "admin" database in the shell:

```http
http://localhost:28017/admin/$cmd/?filter_listDatabases=1&limit=1
```

To count documents in a collection:

```http
http://host:port/db/$cmd/?filter_count=collection&limit=1
```

**JSON in the simple REST interface**

The simple ReST interface uses strict JSON (as opposed to the shell, which uses Dates, regular expressions, etc.). To display non-JSON types, the web interface wraps them in objects and uses the key for the type. For example:

```json
# ObjectIds just become strings
"_id" : "4a8ac6e7fba42c242de5b4f3"

# dates
"date" : { "$date" : 1250609897802 }

# regular expressions
"match" : { "$regex" : "foo", "$options" : "ig" }
```

The code type has not been implemented yet and causes the DB to crash if you try to display it in the browser.

See [Mongo Extended JSON](https://docs.mongodb.com/manual/reference/mongo-extended-json/) for details.

**Replica Set Admin UI**

The mongod process includes a simple administrative UI for checking the status of a replica set.
To use, first enable `--rest` from the `mongod` command line. The rest port is the db port plus 1000 (thus, the default is 28017). Be sure this port is secure before enabling this.

Then you can navigate to `http://<hostname>:28017/` in your web browser. Once there, click Replica Set Status (/_replSet) to move to the Replica Set Status page.

![Replica Set Status](http://localhost:2807/replSet)

#### mongoperf

- Prebuilt Binaries
- Building
- Running
  - `mmf:false` mode (direct i/o test)
  - `mmf:true` mode
- Additional Options
- See Also

mongoperf is a utility for checking disk i/o performance of a server independent of MongoDB. It performs simple timed random disk i/o's. The utility is new and will likely be more sophisticated in the future.

mongoperf can be used to check disk subsystem performance even when MongoDB will not be used at all: its `mmf:false` mode is completely generic. In that mode is it somewhat analogous to tools such as bonnie++ (albeit mongoperf is simpler).

### Prebuilt Binaries

- Win32 24Jul2012 mongoperf.exe
- Linux 64 bit

### Building

Run `scons mongoperf` or `scons mongoperf.exe` to build. Note: mongoperf is new, so will need a recent version of the mongod source code.

### Running
show help:
mongoperf -h

echo "\{nThreads:16,fileSizeMB:1000,r:true\}" | ./mongoperf | tee out

we might do this while it runs:
iostat -x m 2

mffb:default mode (direct i/o test)

In this default mode, mongoperf performs random 4KB direct (physical) disk i/o's (i.e., O_DIRECT is used on Linux). Thus this is a physical disk i/o test.

- Output form an example run

mffb:true mode

If mffb:true is specified as an option, tests are performed using memory-mapped files. These files are opened in a "normal" fashion and thus caching is allowed. This sometimes can be used to test file system cache behavior with memory mapped files.

Additional Options

```
{
    nThreads:<n>, // number of threads (default 1)
    fileSizeMB:<n>, // test file size (default 1MB)
    sleepMicros:<n>, // pause for sleepMicros/nThreads between each operation (default 0)
    mff:<bool>, // if true do i/o's via memory mapped files (default false)
    r:<bool>, // do reads (default false)
    w:<bool>, // do writes (default false)
    syncDelay:<n> // secs between fsyncs, like --syncdelay in mongod. (default 0/never)
}
```

- nThreads Number of test threads. You will need several threads to test a disk subsystem to saturation. For example, try nThreads:16.
- sleepMicros Pause for sleepMicros/nThreads between each operation.
- r Do read operations while testing.
- w Do write options while testing. w and r may be used at the same time.
- syncDelay For use with mff:true mode only. The syncDelay:secs option instructs mongoperf to perform an asynchronous fsync of the test mmap file at the specified interval. mongod does something similar every 60 seconds, thus this can be useful to test basic system behavior in a simpler setting. This option is applicable only when using mff:true mode. Currently in mongoperf this defaults to zero, which means off.
- fileSizeMB. Specifies the size in megabytes of the test data file. The file will be placed in the current directory. Specify a very large test file size to create a realistic simulation. A very small file (1MB) could be cached by your disk controller completely. A file that is say, 100MB in size would involve a small number of disk cylinders, and adjacent track-to-track seeks are much faster than a drive's average seek time. The file size is particularly important when mff:true is specified, as the file system cache is then involved. A file size much larger than RAM will result in much different performance results than a file size smaller than RAM.

- The utility is quite simple, so you might wish to also take a look at the source code.
- iostat

Munin configuration examples

Overview

Munin can be used for monitoring aspects of a running system. The following is a mini tutorial to help you set up and use the MongoDB plugin.
Setup

Munin is made up of two components

- agent and plugins that are installed on the system you want to monitor
- server which polls the agent(s) and creates the basic web pages and graphs to visualize the data

Install

You can download from SourceForge, but prebuilt packages are also available. For example on Ubuntu you can do the following:

Agent install

To install the agent, repeat the following steps on each node you want to monitor.

```shell
sudo apt-get install munin-node
```

Server install

The server needs to be installed once. It relies on apache2, so you will need to ensure that it is installed as well.

```shell
apt-get install apache2
apt-get install munin
```

Configuration

Both the agent(s) and server need to be configured with the IP address and port to contact each other. In the following examples we will use these nodes:

- `db2`: 10.203.22.38
- `munin-server`: 10.194.102.70

Agent configuration

On each node, add an entry as follows into `/etc/munin/munin-node.conf` for `db1`:

```conf
host_name db1-ec2-174-129-52-161.compute-1.amazonaws.com
allow ^10\194\102\70$
```

for `db2`:

```conf
host_name db2-ec2-174-129-52-161.compute-1.amazonaws.com
allow ^10\194\102\70$
```

* `host_name`: can be whatever you like, this name will be used by the server
  * `allow`: this is the IP address of the server, enabling the server to poll the agent

Server configuration

Add an entry for each node that is being monitored as follows in

```conf
```
* the name in between the [] needs to match the name set in the agents munin-node.conf

- address : IP address of the node where the agent is running
- use_node_name : determine if the IP or the name between [] is used to contact the agent

MongoDB munin plugin

A plugin is available that provide metrics for

- B-Tree stats
- Current connections
- Memory usage
- Database operations (inserts, updates, queries etc.)

The plugin can be installed as follows on each node where MongoDB is running

```shell
shell> wget https://github.com/erh/mongo-munin/tarball/master
shell> tar xvf erh-mongo-munin-*.tar.gz
shell> cp erh-mongo-munin-*/*mongo_* /etc/munin/plugins/
```

Check your setup

After installing the plugin and making the configuration changes, force the server to update the information to check your setup is correct using the following

```shell
shell> sudo -u munin /usr/share/munin/munin-update
```

If everything is set up correctly, you will get a chart like this
Advanced charting

If you are running a large MongoDB cluster, you may want to aggregate the values (e.g. inserts per second) across all the nodes in the cluster. Munin provides a simple way to aggregate.

```
/etc/munin/munin.conf
[compute-1.amazonaws.com;CLUSTER]
update no
```

* Defines a new segment called CLUSTER

  * update no: munin can generate the chart based on existing data, this tell munin not to poll the agents for the data

Now lets define a chart to aggregate the inserts, updates and delete for the cluster

```
cluster_ops.graph_title Cluster Ops
cluster_ops.graph_category mongodb
cluster_ops.graph_total total
cluster_ops.total.graph no
cluster_ops.graph_order insert update delete
cluster_ops.insert.label insert
cluster_ops.insert.sum \
  db1-ec2-174-129-52-161.compute-1.amazonaws.com:mongo_ops.insert \\
  db2-ec2-184-72-191-169.compute-1.amazonaws.com:mongo_ops.insert
cluster_ops.update.label update
cluster_ops.update.sum \
  db1-ec2-174-129-52-161.compute-1.amazonaws.com:mongo_ops.update \\
  db2-ec2-184-72-191-169.compute-1.amazonaws.com:mongo_ops.update
cluster_ops.delete.label delete
cluster_ops.delete.sum \
  db1-ec2-174-129-52-161.compute-1.amazonaws.com:mongo_ops.delete \\
  db2-ec2-184-72-191-169.compute-1.amazonaws.com:mongo_ops.delete
```

* cluster_ops: name of this chart

  * cluster_ops.graph_category mongodb: puts this chart into the "mongodb" category. Allows you to collect similar charts on a single page
  * cluster_ops.graph_order insert update delete: indicates the order of the line on the chart
  * cluster_ops.insert: represents a single line on the chart, in this case the "insert"
  * cluster_ops.insert.sum: indicates the values are summed
    * db1-ec2-174-129-52-161.compute-1.amazonaws.com: indicates the node to aggregate
    * mongo_ops.insert: indicates the chart (mongo_ops) and the counter (insert) to aggregate

And this is what it looks like
Windows

Windows Quick Links and Reference Center

Running MongoDB on Windows

See the Quickstart page for info on how to install and run the database for the first time.

Running as a Service

See the Windows Service page.

The MongoDB Server

Get pre-built binaries on the Downloads page. Binaries are available for both 32 bit and 64 bit Windows. MongoDB uses memory-mapped files for data storage, so for servers managing more than 2GB of data you will definitely need the 64 bit version (and a 64 bit version of Windows).

The Windows 2008+ MongoDB build uses newer features of Windows to enhance performance. Use this build if you are running with 64-bit Windows Server 2008 R2, Windows 7, or greater.

Writing Apps

You can write apps in almost any programming language – see the Drivers page. In particular C#, .NET, PHP, C and C++ work just fine.

- CSharp Language Center
- CSharp Community Projects

Building

We recommend using the pre-built binaries, but Mongo builds fine with Visual Studio 2008 and 2010. See the Building for Windows page.

Versions of Windows

We have successfully run MongoDB (mongod etc.) on:

- Windows Server 2008 R2 64 bit
- Windows 7 (32 bit and 64 bit)
- Windows Vista
- Windows XP

⚠️ As of MongoDB Server 2.1.2, Windows XP is no longer supported as a server environment.

Windows Azure

Instructions for running MongoDB on Azure on Azure Worker Role (alpha)
MongoDB Installer for Windows Azure VM

AppHarbor

Instructions for running MongoDB on AppHarbor
Sample ASP.NET MVC app that uses MongoDB from AppHarbor

Wireshark Support for MongoDB Protocol

Wireshark, an advanced interactive network traffic sniffer, has full support for the MongoDB Wire protocol.

You can visually inspect MongoDB traffic, do complex filters on specific values of MongoDB wire messages and dig into individual documents both sent and received.

Note: wireshark looks for port 27017 and infers MongoDB protocol from this. If you are running on a different port number, go to Preferences...Protocols...Mongo and set your port number and it should then interpret the data.
<table>
<thead>
<tr>
<th>Field name</th>
<th>Relation</th>

What's New

- (Dec 2012) SoftLayer offers servers preconfigured and optimized for MongoDB

Database-as-a-Service

- MongoDB.com
- MongoHQ
- MongoLab
- HostedMongo.com
- MongoGrid
- ObjectRocket - MongoDB service provider specializing in high performance and availability.
- MongoDB by GrandCloud (China)
- MongoHosting.com

Infrastructure-as-a-Service

- Amazon EC2
- Joyent
- Rackspace Cloud
- Windows Azure VM

Dedicated Servers / Hosting

MongoDB runs well on both virtualized and non-virtualized servers.

- ServerBeach offers preconfigured, dedicated MongoDB servers. Blog
Platform-as-a-Service

- alwaysdata
- cloudControl offers a fully managed platform-as-a-service solution with MongoDB as one of their powerful add-ons. Read the blog post MongoDB Setup at cloudControl for more information.
- dotCloud
- Heroku has add-on connectors to allow you to use from MongoDB from Heroku applications
- NodeGrid
- RedHat OpenShift supports MongoDB
- VMware CloudFoundry supports MongoDB
- Windows Azure Cloud Services

VPS

- (mt) Media Temple's (ve) server platform is an excellent choice for easy MongoDB deployment.
- A2 Hosting has a quick installer to add MongoDB to your VPS hosting account. Instructions for running the installer are on A2's wiki
- Dreamhost offers instant configuration and deployment of MongoDB
- LOCUM Hosting House is a project-oriented shared hosting and VDS. MongoDB is available for all customers as a part of their subscription plan.

MongoDB runs well on Amazon EC2. This page includes some notes in this regard.

Getting Started on EC2

This guide is intended to provide instructions on using the MongoDB AMI to set up production instances of MongoDB across Amazon's Web Services (AWS) EC2 infrastructure.

First, we'll step through deployment planning (instance specifications, deployment size, etc.) and then we'll set up a single production node. We'll use those setup steps to deploy a three node MongoDB replica set for production use. Finally, we'll briefly cover some advanced topics such as multi-region availability and data backups.

See the Amazon EC2 Quickstart guide for more information.
Backup, Restore, Verify

Depending upon the configuration of your EC2 instances, there are a number of ways to conduct regular backups of your data. For specific instructions on backing up, restoring and verifying refer to EC2 Backup & Restore.

Deployment Notes

MongoDB via AWS Marketplace

If you installed MongoDB via the AWS Marketplace refer to the MongoDB via AWS Marketplace guide to get a development instance up and running. If you are interested in creating a production deployment, refer to the Amazon EC2 Quickstart. Start with the section on Configuring Storage to set up a place for your data to be stored. After that refer to the Starting MongoDB section to get your MongoDB instance running. If you're interested in scaling your deployment, check out the sections on Replica Sets and Sharding.

Automating Deployment with CloudFormation

CloudFormation from Amazon Web Services provides an easy mechanism to create and manage a collection of AWS resources. To use CloudFormation you create and deploy a template which describes the resources in your stack via the AWS Management Console. We have created a series of reference templates that you can use as a starting point to build your own MongoDB deployments using CloudFormation. Check out Automating Deployment with CloudFormation for a walkthrough and the template files.

Instance Types

MongoDB works on most EC2 types including Linux and Windows. We recommend you use a 64 bit instance as this is required for all MongoDB databases of significant size. Additionally, we find that the larger instances tend to be on the freshest ec2 hardware.

Installing MongoDB

One can download a binary or build from source. Generally it is easier to download a binary. We can download and run the binary without being root. For example on 64 bit Linux:

```
[-]$ curl --o http://downloads.mongodb.org/linux/mongodb-linux-x86_64-1.0.1.tgz
[-]$ tar -xzf mongodb-linux-x86_64-1.0.1.tgz
[-]$ cd mongodb-linux-x86_64-1.0.1/bin
[bin]$ ./mongod --version
```

Before running the database one should decide where to put datafiles. Run df -h to see volumes. On some images /mnt will be the many locally attached storage volume. Alternatively you may want to use Elastic Block Store which will have a different mount point.

If you mount the file-system, ensure that you mount with the noatime and nodiratime attributes, for example

```
/dev/mapper/my_vol /var/lib/mongodb xfs noatime,nowexec,nodiratime 0 0
```

Create the mongodb datafile directory in the desired location and then run the database:

```
mkdir /mnt/db
./mongod --fork --logpath ~/mongod.log --dbpath /mnt/db/
```

Operating System

Occasionally, due to the shared and virtualized nature of EC2, an instance can experience intermittent I/O problems and low responsiveness compared to other similar instances. Terminating the instance and bringing up a new one can in some cases result in better performance.

Some people have reported problems with ubuntu 10.04 on ec2.

Please read here and here for further information.

Networking

Port Management

By default the database will now be listening on port 27017. The web administrative UI will be on port 28017.
Keepalive

Change the default TCP keepalive time to 300 seconds. See our troubleshooting page for details.

Storage Configuration

For production use, we recommend raid 10 across 4-8 ebs drives for best performance. Local ec2 drives may be faster but are generally not suitable as they are ephemeral. Multiple ebs drives increase the potential number of random IO's per second (iops), but not necessarily sequential read/write throughput much. In most database applications random iops are important.

For more information, refer to EBS info at Amazon Web Services.

EBS Snapshots

If your datafiles are on a single EBS volume, you can snapshot them for backups.

If you are using journaling, simply take a snapshot (including the journal/ directory).

If not using journaling, you need to use the lock+fsync command (v1.3.1+).

Use this command to lock the database to prevent writes. Then, snapshot the volume. Then use the unlock command to allow writes to the database again. See the full EC2 Backup, Verify & Recovery guide for more information. This method may also be used with slaves / secondaries.

Securing instances

Restrict access to your instances by using the Security Groups feature within AWS. A Security Group is a set of firewall rules for incoming packets that can apply to TCP, UDP or ICMP.

A common approach is to create a MongoDB security group that contains the nodes of your cluster (replica set members or sharded cluster members), followed by the creation of a separate security group for your app servers or clients.

Create a rule in your MongoDB security group with the "source" field set to the Security Group name containing your app servers and the port set to 27017 (or whatever port you use for your MongoDB). This will ensure that only your app servers have permission to connect to your MongoDB instances.

Remember that Security Groups only control ingress traffic.

Communication across regions

Every EC2 instance will have a private IP address that can be used to communicate within the EC2 network. It is also possible to assign a public "elastic" IP to communicate with the servers from another network. If using different EC2 regions, servers can only communicate via public IPs.

To set up a cluster of servers that spans multiple regions, it is recommended to cname the server hostname to the "public dns name" provided by EC2. This will ensure that servers from a different network use the public IP, while the local servers use the private IP, thereby saving costs. This is required since EC2 security groups are local to a region.

To control communications between instances in different regions (for example, if you have two members of a replica set in one region and a third member in another), it is possible to use a built-in firewall (such as iptables on Linux) to restrict allowed traffic to certain (elastic) IP addresses or ports.

For example one solution is following, on each server:

- set the hostname of the server
  
  ```bash
  sudo hostname server1
  ```

- install "bind", it will serve as local resolver
- add a zone for your domain, say "myorg.com", and add the CNAMEs for all your servers

  ```
  ...  
  ```

- restart bind and modify /etc/resolv.conf to use the local bind
search myorg.conf
nameserver 127.0.0.1

Then:

- verify that you can properly resolve server1, server2, ... using a tool like dig.
- when running mongod, db.serverStatus() should show the correct hostname, e.g. "server1:27017".
- you can then set up replica sets or shards using the simple hostname. For example connect to server1 and run "rs.initiate()", then "rs.add('server2:27017')".

AWS Marketplace

- Starting MongoDB
- Security Setup
- Instance Configurations
  - MongoDB AMI
  - MongoDB with EBS RAID AMI
- More Information

If you installed MongoDB via the AWS Marketplace, refer to the instructions below for Starting MongoDB. For information on how the MongoDB with instance-storage AMI was configured, see MongoDB AMI. For information on how the MongoDB with EBS RAID storage was configured, see MongoDB with EBS RAID AMI. The Security Setup section contains information about the security group settings for these AMIs.

Starting MongoDB

The instance has been mostly configured, the only steps left are to set MongoDB to start at system boot and then start mongod up:

```
$ sudo chkconfig mongod on
$ sudo /etc/init.d/mongod start
Starting mongod: [ OK ]
forked process: 1234
all output going to: /log/mongod.log
```

In a few moments MongoDB will finish starting up and then you can connect to MongoDB using the mongo client:

```
$ mongo
MongoDB shell version: 2.0.4
connecting to: test
>
```

If you have trouble connecting to the MongoDB daemon, check the log file (either /var/log/mongo/mongod.log or /log/mongod.log) for mongod console output.

Security Setup

By default, the instance starts up with a newly created security group and that group specifies that only access via port 22 (SSH) is allowed. In order to make MongoDB accessible to other instances, you'll need to add an additional rule to your security group specifying access to port 27017.
along with a source (this can be a specific IP address, instances from within another security group or from an IP). Start by logging in to the AWS EC2 Management Console and navigate to the Security Groups section. Next, find the group that was created when you created your instance and add an Inbound Rule:

![Security Group](image)

After the rule is applied, you’ll be able to access MongoDB running in your instance from the source you specified. Consult the AWS EC2 Security Groups documentation for more information about configuring access to your instance with security groups.

**Instance Configurations**

**MongoDB AMI**

MongoDB was installed onto Amazon Linux using a subset of steps found in the Install MongoDB section of the EC2 Quickstart guide. Specifically, the 10gen repository was created and MongoDB (along with sysstat tools) were then installed via yum. This AMI uses a single EBS-backed volume as storage and does not employ RAID10 or LVM. The data directory was set to `/data` in the MongoDB configuration file `/etc/mongodb.conf`.

**MongoDB with EBS RAID AMI**

Using the Amazon EC2 Quickstart guide as a base, the EBS RAID AMI was configured using a subset of the steps found in the Deploying a Single Node section. This AMI was configured with block device mapping and uses 4 EBS volumes, each with 100GiB of storage. The volumes were then setup as a single RAID10 device using `mdadm` and 3 logical volumes (data, log, journal) were created using LVM. With RAID10 the total available storage is 200GiB and within that 180GiB is for `/data`, 10GiB for `/log` and 10GiB for `/journal`. The MongoDB configuration file `/etc/mongod.conf` reflects the updated locations for these elements. For more information on the specific steps, refer to the Amazon EC2 Quickstart guide.

**More Information**

For more information on deploying MongoDB on AWS (including advanced storage setups, backups, etc.), refer to the Amazon EC2 page or the Amazon EC2 Quickstart guide.

**Automating Deployment with CloudFormation**

- Template Walkthrough
  - Security
  - Storage Configuration
  - Instance Configuration
- Replica Set Stack
- Customizing Templates
  - Operating System
  - Storage
  - Instances
- Sample Template Usage

CloudFormation from Amazon Web Services provides an easy mechanism to create and manage a collection of AWS resources. To use CloudFormation you create and deploy a template which describes the resources in your stack via the AWS Management Console. CloudFormation templates are simple JSON formatted text files that can be placed under your normal source control mechanisms, stored in private or public locations such as Amazon S3.

We have created a series of reference templates (see attachments below) that you can use as a starting point to build your own MongoDB deployments using CloudFormation. The sample templates show how to build a single node MongoDB deployment and a MongoDB replica set deployment. Refer to the following sections for information on how these sample templates were developed and instructions on how to customize them for your own deployment onto AWS. The documentation provided below focuses on the sections specific to deploying MongoDB on AWS, for background on standard template sections (e.g. input parameters) refer to the AWS CloudFormation User Guide.

The sample templates we created are as follows (click to download):
• MongoDB_SingleNode.template is an example single-node MongoDB deployment with 4 EBS volumes
• MongoDB_ReplicaSetStack.template sets up a single node and references the...
• MongoDB_ReplicaSetMember.template twice to create the additional nodes (each node has 4 EBS volumes)

Template Walkthrough

Security

EC2 instances in AWS must have security groups designated during creation that specify firewall rules for each instance. In our templates, we create a simple security group MongoDBSecurityGroup that opens up port 22 (SSH) to the outside world and a separate rule (AWS::EC2::SecurityGroupIngress) that's used to open up the standard mongod port (27017) to other instances within that group:

```
"MongoSecurityGroup" : {
  "Type" : "AWS::EC2::SecurityGroup",
  "Properties" : {
    "GroupDescription" : "MongoDB security group",
    "SecurityGroupIngress" : [
      { "IpProtocol" : "tcp",
        "FromPort" : "22",
        "ToPort" : "22",
        "CidrIp" : "0.0.0.0/0"
      }
    ],
    "MongoSecurityGroupIngress" : {
      "Type" : "AWS::EC2::SecurityGroupIngress",
      "Properties" : {
        "GroupName" : { "Ref" : "MongoSecurityGroup" },
        "IpProtocol" : "tcp",
        "FromPort" : "27017",
        "ToPort" : "27017",
        "SourceSecurityGroupName" : { "Ref" : "MongoSecurityGroup" }
      }
    }
  }
},

"MongoVolume1" : {
  "Type" : "AWS::EC2::Volume",
  "Properties" : {
    "Size" : { "Ref" : "VolumeSize" },
    "AvailabilityZone" : [ "Fn::GetAtt" : [ "MongoInstance", "AvailabilityZone" ]]
  }
},
```

Depending on the type of deployment you are creating, you may need to add additional security group ingress rules to open up additional ports, available to your instances or to the outside world (e.g. port 27018 for sharding).

Storage Configuration

When using MongoDB on AWS, we recommend using multiple EBS volumes configured as a single RAID10 storage device for your data. Configuring storage via EBS volumes using CloudFormation requires multiple steps. First the EBS volume must be created, using the VolumeSize input value and the same availability zone that we'll use for our EC2 instance (see Instance Configuration):

```
```

The next step is to attach the volume to an EC2 instance. By referencing the instance name in "Instanceld" we ensure that the EBS volumes will be created after the instance is created.
In the attached sample templates we used 4 EBS volumes as the basis for our RAID10 configuration. If you are interested in increasing the number of EBS volumes, you will need to add additional AWS::EC2::Volume and AWS::EC2::VolumeAttachment resources inside of your template. Refer to the Customizing Storage section below for more information on the steps required.

**Instance Configuration**

The centerpiece of the CloudFormation template is the creation of the EC2 instances that will be used as the MongoDB server. There are two main sections to be configured for your instance, the instance metadata and instance properties. In the sample provided, the metadata contains information about the packages to be installed (mdadm and sysstat) and any files to be created within the instance. In our sample, the only file to be created is a yum repository entry to facilitate MongoDB being installed via yum after the instance has booted.

For more information about the possible options for the metadata section, refer to the CloudFormation documentation for the AWS::EC2::Instance resource. The properties section in the template is used to specify things like the instance type, AMI, security groups and a script to be run after boot (found in the "UserData" section):
The instance type is determined by the `InstanceType` input parameter. The "ImageId" specifies the AMI to use, which is determined by the chosen instance type (e.g. `m1.large`) and region in which the instance is launched (e.g. `us-east-1`). Refer to the "Mappings" section inside the sample templates for a list of the available AMIs.

The "UserData" section shown above contains a bash script that be executed once the instance is launched and available. The first step is install the `aws-cfn-bootstrap` tools which are used in the script to initialize the instance, signal when errors have occurred and when the the instance creation is complete:

```
"yum update -y aws-cfn-bootstrap"

"## Error reporting helper function"
"function error_exit"
"("\n",
"   /opt/aws/bin/cfn-signal -e 1 -r "$1" "\n", { "Ref" : "WaitHandleMongoInstance" }, "\n",
"   exit 1"\n",
"
",
"## Initialize CloudFormation bits"
"/opt/aws/bin/cfn-init -v -s "$AWS::StackName" -r MongoInstance",
"   --access-key "$HostKeys",
"   --secret-key "Fn::GetAtt: ["HostKeys", "SecretAccessKey"]",
"   --region "$AWS::Region" > /tmp/cfn-init.log 2>&1 || error_exit $('</tmp/cfn-init.log)"

Next we include a series of sleep conditions in case our EBS volumes are not yet available. If you plan to use more than 4 EBS volumes in your CloudFormation template, you should add additional sleep conditions here:

```
"## Waiting EBS mounts to become available"
"while [ ! -e /dev/sdh1 ]; do echo waiting for /dev/sdh1 to attach; sleep 10; done"
"while [ ! -e /dev/sdh2 ]; do echo waiting for /dev/sdh2 to attach; sleep 10; done"
"while [ ! -e /dev/sdh3 ]; do echo waiting for /dev/sdh3 to attach; sleep 10; done"
"while [ ! -e /dev/sdh4 ]; do echo waiting for /dev/sdh4 to attach; sleep 10; done"
```

Then we install MongoDB and create the RAID10 device:

```
"yum -y install mongo-10gen-server > /tmp/yum-mongo.log 2>&1"

"## Create RAID10 and persist configuration"
"mdadm --verbose --create /dev/md0 --level=10 --chunk=256 --raid-devices=4 /dev/sdh1 /dev/sdh2 /dev/sdh3 /dev/sdh4 > /tmp/mdadm.log 2>&1"
"echo 'mdadm --detail --scan' | tee -a /etc/mdadm.conf"
```

With the RAID10 created, we can set some block device attributes (read-ahead) for each storage device:

```
"## Set read-ahead on each device"
"blockdev --setra 128 /dev/md0"
"blockdev --setra 128 /dev/sdh1"
"blockdev --setra 128 /dev/sdh2"
"blockdev --setra 128 /dev/sdh3"
"blockdev --setra 128 /dev/sdh4"
```

Now we use LVM to create a series of logical volumes for data, journal and logs. The values used below for each volume are specified as percentages, those may need to be changed for your deployment. After creating the volumes, we create the filesystem, mount points and entries in the filesystem table. The last storage-related step is to set the user:group ownership of each mount point to `mongodb:mongodb`.
"## Create physical and logical volumes"
"dd if=/dev/zero of=/dev/md0 bs=512 count=1
"pvcreate /dev/md0
"vgcreate vg0 /dev/md0
"lvcreate -l 90%vg -n data vg0
"lvcreate -l 5%vg -n log vg0
"lvcreate -l 5%vg -n journal vg0

"## Create filesystems and mount point info"
"mke2fs -t ext4 -F /dev/vg0/data > /tmp/mke2fs1.log 2>&1
"mke2fs -t ext4 -F /dev/vg0/log > /tmp/mke2fs2.log 2>&1
"mke2fs -t ext4 -F /dev/vg0/journal > /tmp/mke2fs3.log 2>&1

"mkdir /data
"mkdir /log
"mkdir /journal

"echo '/dev/vg0/data /data ext4 defaults,auto,noatime,noexec 0 0' | tee -a /etc/fstab
"echo '/dev/vg0/log /log ext4 defaults,auto,noatime,noexec 0 0' | tee -a /etc/fstab
"echo '/dev/vg0/journal /journal ext4 defaults,auto,noatime,noexec 0 0' | tee -a /etc/fstab

"mount /data > /tmp/mount1.log 2>&1
"mount /log > /tmp/mount2.log 2>&1
"mount /journal > /tmp/mount3.log 2>&1

"ln -s /journal /data/journal

"chown -R mongod:mongod /data
"chown -R mongod:mongod /log
"chown -R mongod:mongod /journal

Next we proceed to creating a MongoDB configuration file, specifying the logpath and data directory (among others), and start MongoDB:

"## Update mongod configuration"
"cat <<EOF > /etc/mongod.conf
"logpath=/data/log/mongod.log
"logappend=true
"fork=true
"dbpath=/data
"rest=true
"EOF

"## Start mongod"
"/etc/init.d/mongod start > /tmp/mongod-start.log 2>&1

The final step is to signal our previously created WaitCondition that setup is complete:

"## CloudFormation signal that setup is complete"
"/opt/aws/bin/cfn-signal -e 0 -r "'MongoInstance setup complete" "', { "Ref" : "WaitHandleMongoInstance" }, "\n"

Once this script has completed executing, the instance and associated resources have been created and our CloudFormation stack is ready to go.

**Replica Set Stack**

The "ReplicaSetStack" sample template first creates two "ReplicaSetMember" instances (complete with storage configuration) and then creates the overall replica set. The "ReplicaSetMember" template is modeled very closely after the "SingleNode" template except it includes additional input parameters and adds additional commands to the instance setup script in "UserData" specific to creating replica set members (adding in the replSet parameter to the MongoDB configuration file).
The "ReplicaSetStack" template also closely follows the "SingleNode" template but adds the following replica set specific steps: (1) it creates a "replicaSetConfigInit.js" file containing the replica set configuration (with hostnames for the additional members) and (2) initiates the replica set. These steps are executed just prior to signaling that the instance setup has been completed:

```
cat <<EOF > /tmp/replicaSetConfigInit.js
config = { _id: "", "ReplicaSetName": "", members: [ {
  "id": 0, host: "$HOSTNAME:27017"}, {
  "id": 1, host: "$HOSTNAME:27017"}, {
  "id": 2, host: "$HOSTNAME:27017"}],
rs.initiate(config);
EOF
```

```
/usr/bin/mongo /tmp/replicaSetConfigInit.js > /tmp/replica-setup.log 2>&1
```

The child "ReplicaSetMember" instances are created from within the "ReplicaSetStack" template using the following resource definition. The inputs for the "ReplicaSetMember" instances are taken from the "ReplicaSetStack" template:

```
"ReplicaSetMember1" : { 
  "Type" : "AWS::CloudFormation::Stack", 
  "Properties" : { 
    "TemplateURL" : "http://S3URL/MongoDB_ReplicaSetMember.template", 
    "Parameters" : { 
      "KeyName" : { "Ref" : "KeyName" }, 
      "InstanceType" : { "Ref" : "InstanceType" }, 
      "VolumeSize" : { "Ref" : "VolumeSize" }, 
      "AccessKeyId" : { "Ref" : "AccessKey" }, 
      "ReplicaSetName" : { "Ref" : "ReplicaSetName" }, 
      "InstanceZone" : { "Fn::FindInMap" : [ "RegionZone", [ "Ref" : "AWS::Region" ], "AZ1" ] } 
    } 
  } 
}
```

**Customizing Templates**

**Operating System**

In the sample templates provided, we used Amazon Linux as the base operating system. If you are interested in using a recent release of Ubuntu (9.10 or greater), please use the following steps to customize the templates. The steps refer to the line numbers for the MongoDB_ReplicaSetStack.template but changes should also be made in MongoDB_ReplicaSetMember.template.

First, update the "files" content of the EC2 instance Metadata section to use the 10gen apt source:
Then in the UserData section of the EC2 instance configuration, make the following changes:

- Line 220: change `yum -y install mongo-10gen-server...` to `apt-get install mongodb-10gen`
- Line 221: add `service mongodb stop`
- Line 260, 261, 262: update to use `mongodb:mongodb` as the owner:group
- Line 265: update to `cat <<EOF > /etc/mongodb.conf`
- Line 275: change `/etc/init.d/mongod start...` to `service mongodb start`

### Storage

In the sample templates provided, we used 4 EBS volumes as the basis for our RAID10 configuration. If you are interested in using additional volumes you will need to update the following items for each new volume you want to add:

- Add an "AWS::EC2::Volume" resource
- Add an "AWS::EC2::VolumeAttachment" resource and mount point
- Add an additional sleep condition
- Update the call to `mdadm` to include your additional volumes

### Instances

The sample "ReplicaSetStack" template creates three instances, one from the "stack" template and two additional "ReplicaSetMember" instances, via the "AWS::CloudFormation::Stack" resource in the "ReplicaSetStack" template. If you are interested in adding additional replica set members, you'll need to create an additional member instances and edit the `replicaSetConfigInit.js` found within the "ReplicaSetStack" template. Refer to the Replica Set Stack for information about the additional resources and config file to be updated. When creating the replica set the templates spread the created instances across multiple availability zones (e.g. `us-east-1a` or `us-east-1b`). When adding additional instances be sure to specify your desired Availability Zone for increase redundancy.

### Sample Template Usage

If you are interesting in launching a single MongoDB node in AWS, download the `MongoDB_SingleNode.template` file and edit it for your specific `MongoDB_SingleNode.template` deployment. Once you have a completed template, login to the AWS Management Console and navigate to the "AWS CloudFormation" and "Create New Stack". There you'll be prompted to upload your template and input the necessary parameters.

If instead you are interested in launching a multi-node replica set, download the `MongoDB_ReplicaSetStack.template` and `MongoDB_ReplicaSetMember.template`. In order for a parent template ("ReplicaSetStack") to refer to child templates ("ReplicaSetMember"), the child template must be uploaded to S3 and the S3 URL of the child template must be specified in the parent template. Once you've uploaded the child template to S3, update the "TemplateURL" parameter in each "ReplicaSetMember" resource in the "ReplicaSetStack" template:
After updating the "TemplateURL" parameters, login to the AWS Management Console and navigate to the "AWS CloudFormation" and "Create New Stack". There you'll be prompted to upload your template and input the necessary parameters.

For more information on deploying MongoDB on AWS, refer to the Amazon EC2 page and the Amazon EC2 Quickstart guide.

**Amazon EC2 Quickstart**

- **Prerequisites**
- **Planning Your Deployment**
  - Instance Specifications
  - Storage Configuration
  - Topology
  - Security
- **Securing Your Deployment**
- **Deploying a Single Node**
  - Launch Instance
  - Configure Storage
  - Install and Configure MongoDB
  - Starting MongoDB
- **Deploying a Multi-node Replica Set**
  - Replica Set Background
  - Create and Configure Instances
  - Configure Replica Set
- **Deploying a Sharded Configuration**
  - Simple Sharding Architecture
- **Backup and Restore**

This guide is intended to provide instructions on setting up production instances of MongoDB across Amazon's Web Services (AWS) EC2 infrastructure.

First, we'll step through deployment planning (instance specifications, deployment size, etc.) and then we'll set up a single production node. We'll use those setup steps to deploy a three node MongoDB replica set for production use. Finally, we'll briefly cover some advanced topics such as multi-region availability and data backups.

If you installed MongoDB via the AWS Marketplace, this guide can be used to get your instance up and running quickly. Start with the section on Configuring Storage to set up a place for your data to be stored. After that refer to the Starting MongoDB section to get your instance started and allow you to get started using MongoDB. If you're interested in scaling your deployment, check out the sections on Replica Sets and Sharding below.

**Prerequisites**

Generally, there are two ways to work with EC2 - via the command line tools or the AWS Management Console. This guide will use the EC2 command line tools to manage security and storage and launch instances. Use the following steps to setup the EC2 tools on your system:

- Download the EC2 command line tools
- Next, refer to Prerequisites and Setting Up the Tools from Amazon's Getting Started with the Command Line Tools

**Planning Your Deployment**

Before starting up your EC2 instances, it's best to sketch out a few details of the planned deployment. Regardless of the configuration or the number of nodes in your deployment, we'll configure each one in roughly the same manner.

**Instance Specifications**

Amazon has several instance choices available ranging from low to high (based on CPU and memory) throughput. Each instance available serves a different purpose and plays a different role when planning your deployment. There are several roles to consider when deploying a MongoDB production cluster. Consider a situation where your deployment contains an even number of replicated data (mongod) instances, an arbiter participates in electing the primary but doesn't hold any data. Therefore a Small instance may be appropriate for the arbiter role but for data nodes you'll want to use 64-bit (standard Large or higher) instances, which have greater CPU and memory scaling. For the purposes of this guide we'll be focused on deploying mongod instances that use the standard Large instance. The AMI (ID: ami-41814f28) is the 64-bit base Amazon Linux, upon which we'll install MongoDB.

**Storage Configuration**

For storage we recommend using multiple EBS volumes (as opposed to instance-based storage which is ephemeral) in a RAID-based configuration. Specifically for production deployments you should use RAID 10 across 4-8 EBS volumes for the best performance. When deploying RAID 10, you'll need enough volume storage to be twice that of the desired available storage for MongoDB. Therefore for 8 GiB of available storage you'll need to have 16 GiB of allocated storage space across multiple EBS volumes.

**Topology**
For the purposes of this guide, our topology will be somewhat simple: one to three EC2 instances, each with multiple EBS volumes attached, all located in the same availability zone (and by extension, within the same region). If you are interested in creating a deployment that spans availability zones or regions, it's best to do that planning up front and take into account security group designations (they cannot span regions) and hostname/DNS access (AWS internal IP addresses can only be used within a zone).

An example 3 node replica set with RAID 10 storage, spanning multiple availability zones would like similar to the following. Availability zones within EC2 are similar to different server racks, therefore it is recommended that you deploy your replica set across multiple zones.

For even greater redundancy and failover, you could also deploy your replica set across multiple regions (and go further with multiple zones in each region):

Refer to the AWS documentation on Using Regions and Availability Zones for more information.

**Security**

The recommended approach to securing your instances is to use multiple security groups for your MongoDB deployment, one for each type of interaction. For example, you could use one group to manage communication amongst the nodes in your cluster, another group that allows your application to communicate with the database and optionally, a group for tools and maintenance tasks.

An example setup with two security groups might look like this:
Securing Your Deployment

Before starting up instances we want to get the security groups created. As previously discussed, we recommend using multiple groups, one for each type of interaction. The following steps will show you how to create two groups (one for your app and another for your database) and provide the authorizations necessary for communication between them.

From the command line, create the database group and authorize SSH:

\[
\text{
\$ ec2-create-group database --description "security group for database"
GROUP sg-0814f660 database security group for database
\}$
\[
\text{
\$ ec2-authorize database -p 22
GROUP database
PERMISSION database ALLOWS tcp 22 22 FROM CIDR 0.0.0.0/0 ingress
\}$
\]

Authorize communication within the group of MongoDB instances by adding the group to itself. Note you'll need to provide the user account number (using the \(-u\) flag) when authorizing groups:

\[
\text{
\$ ec2-authorize database -o database -u [AWS_ACCOUNT_NUMBER]
GROUP database
PERMISSION database ALLOWS tcp 0 65535 FROM USER AWS_ACCOUNT_NUMBER NAME database ingress
PERMISSION database ALLOWS udp 0 65535 FROM USER AWS_ACCOUNT_NUMBER NAME database ingress
PERMISSION database ALLOWS icmp -1 -1 FROM USER AWS_ACCOUNT_NUMBER NAME database ingress
\}$
\]

Optionally, for testing you could also enable the port for the MongoDB web-based status interface (port 28017):

\[
\text{
\$ ec2-authorize database -p 28017
GROUP database
PERMISSION database ALLOWS tcp 28017 28017 FROM CIDR 0.0.0.0/0 ingress
\}$
\]

Now create a group that will hold application servers, which will communicate with the database cluster:

\[
\text{
\$ ec2-create-group application --description "security group for application servers"
GROUP sg-081bf960 application security group
\}$
\]

Finally, authorize communication from the application servers (group application) to the MongoDB instances (group database):

\[
\text{
\$ ec2-authorize database -o application -u [AWS_ACCOUNT_NUMBER]
GROUP database
PERMISSION database ALLOWS tcp 0 65535 FROM USER AWS_ACCOUNT_NUMBER NAME application ingress
PERMISSION database ALLOWS udp 0 65535 FROM USER AWS_ACCOUNT_NUMBER NAME application ingress
PERMISSION database ALLOWS icmp -1 -1 FROM USER AWS_ACCOUNT_NUMBER NAME application ingress
\}$
\]

Refer to the AWS guide Using Security Groups for more information on creating and managing security groups.

The next step is to generate an SSH key-pair that we'll use to connect to our running EC2 instances. Amazon's tools provide a mechanism to quickly generate a public-private key pair. Once generated, we'll need to save the private key so that we can use it to connect via SSH later (click here for more info on key pairs and AWS).

First, generate the key pair:
Save the contents of the key to a file (including the \texttt{BEGIN} and \texttt{END} lines) and make sure that file is only readable by you:

\begin{verbatim}
$ chmod 600 private-key-file
\end{verbatim}

Optionally, you can also add the key to the SSH agent to ease connecting to our instances later:

\begin{verbatim}
$ ssh-add private-key-file
\end{verbatim}

We're finished with the pre-deployment steps; we've covered the storage and security considerations that's necessary to setup and deploy our instances.

\textbf{Deploying a Single Node}

We'll start our deployment by setting up single node because later on we'll use the same steps to set up a larger cluster. The first step is to launch the instance and then setup the EBS-backed RAID 10 storage for the instance. Setting up the storage requires creating, attaching, configuring and formatting the volumes where our data will be stored.

\textbf{Configure Storage}

Launch Instance

From the command line we can launch the instance. We'll need to supply an ID for an Amazon Machine Image (AMI) that we'll build our node from. We recommend using a 64-bit Amazon Linux AMI as the base of your MongoDB nodes. In this example, we are using \texttt{ami-e565ba8c} with the number of nodes (1), security group (database), authentication keypair (cluster-keypair), type of instance (m1.large) and availability zone (us-east-1a). Depending on the region you deploy into, a different AMI ID may be needed:

\begin{verbatim}
$ ec2-run-instances ami-e565ba8c -n 1 -g database -k cluster-keypair -t m1.large -z us-east-1a
\end{verbatim}

Next, let's add some tags to the instance so we can identify it later. Tags are just metadata key-value pairs:

\begin{verbatim}
$ ec2-create-tags i-11eee072 --tag Name=QuickstartTestNode --tag Owner=Bob
\end{verbatim}

Now we can ascertain some status information about running instances at AWS (includes EBS volumes as well):
$ ec2-describe-instances

RESERVATION r-f57f8094  711489243244    database
INSTANCE i-a3323dc0  ami-e565ba8c  ec2-107-20-68-113.compute-1.amazonaws.com
ip-10-2-182-67.eu-west-1.compute.internal running cluster-keypair 0       m1.large    2011-12-06T23:18:18+0000
us-east-1c  aki-825ea7eb  monitoring-disabled 107.20.68.113     ebs
paravirtual xen     sg-0814f660, sg-1e15f776  default
BLOCKDEVICE /dev/sda1   vol-2348cf4e  2011-12-06T23:18:43.000Z

Configure Storage

Now that the instance is running, let's create the EBS volumes we'll use for storing our data. In this guide we'll set up 4 volumes with 4 GiB of storage each (configured that's 16 GiB but we're using a RAID 10 configuration that will become 8 GiB of available storage).

First off, create the EBS volumes supplying the size (4) and zone (us-east-1a) and save the results into a temporary file that we'll read from for the next command. Here's the command we'll use:

```bash
$ for x in {1..4}; do \n  > ec2-create-volume -s 4 -z us-east-1a; \n  > done > vols.txt
```

Here's the output of that command:

```bash
$ more vols.txt
VOLUME  vol-e796108a    4               us-east-1a      creating        2011-12-07T04:37:21+0000
VOLUME  vol-c39610ae    4               us-east-1a      creating        2011-12-07T04:37:30+0000
VOLUME  vol-a19610cc    4               us-east-1a      creating        2011-12-07T04:37:39+0000
VOLUME  vol-b19610dc    4               us-east-1a      creating        2011-12-07T04:37:47+0000
```

Now, let's attach those newly created volumes to our previously launched running instance from above. From the command line we'll start with the temp file (vols.txt), the running instance ID (i-11eee072), and a prefix for each attached device (/dev/sdh):

```bash
$ (i=0; \n  > for vol in $(awk '{print $2}' vols.txt); do \n  >  i=$((i+1)); \n  >  ec2-attach-volume $vol -i i-11eee072 -d /dev/sdh${i}; \n  > done)
```

Assuming the volumes attached successfully, you should see something like this:

```bash
ATTACHMENT  vol-e796108a    i-11eee072    /dev/sdh1   attaching   2011-12-07T04:38:22+0000
ATTACHMENT  vol-c39610ae    i-11eee072    /dev/sdh2   attaching   2011-12-07T04:38:29+0000
ATTACHMENT  vol-a19610cc    i-11eee072    /dev/sdh3   attaching   2011-12-07T04:38:37+0000
ATTACHMENT  vol-b19610dc    i-11eee072    /dev/sdh4   attaching   2011-12-07T04:38:44+0000
```

Now we'll need to connect to the running instance via SSH and configure those attached volumes as a RAID array. If you added the private key to your running SSH agent, you should be able to connect with something like (substituting your instance's hostname):

```bash
$ ssh ec2-user@ec2-a-b-c-d.amazonaws.com
```

And now create the RAID array using the built-in mdadm. You'll need the level (10), number of volumes (4), name of the new device (/dev/md0) and the attached device prefix (/dev/sdh*):

```bash
$ mdadm --create /dev/md0 --level=10 --raid-devices=4 --name=md0 /dev/sdh*/
```
Once `mdadm` is done and we've persisted the storage configuration, we'll need to tune the EBS volumes to achieve desired performance levels. This tuning is done by setting the "read-ahead" on each device. For more information refer to the `blockdev man page`.

```
$ sudo mke2fs -t ext4 -F /dev/vg0/data
$ sudo mke2fs -t ext4 -F /dev/vg0/log
$ sudo mke2fs -t ext4 -F /dev/vg0/journal
```

Now mount all of the storage devices. By adding the entry to `/etc/fstab`, we've shortened the call to mount because it will look in that file for extended command parameters.

```
$ sudo mount /data
$ sudo mount /log
$ sudo mount /journal
```
With the devices mounted we issue one last call to set the MongoDB journal files to be written to our new journal device, via a symbolic link to the new device:

```
$ sudo ln -s /journal /data/journal
```

### Install and Configure MongoDB

**Note:** If you created a MongoDB instance via the AWS Marketplace, skip ahead to Starting MongoDB below.

Now that the storage has been configured, we need to install and configure MongoDB to use the storage we've set up, then set it to start up on boot automatically. First, add an entry to the local `yum` repository for MongoDB:

```
$ echo "[10gen]
name=10gen Repository
baseurl=http://downloads-distro.mongodb.org/repo/redhat/os/x86_64
gpgcheck=0" | sudo tee -a /etc/yum.repos.d/10gen.repo
```

Next, install MongoDB and the `sysstat` diagnostic tools:

```
$ sudo yum -y install mongo-10gen-server
$ sudo yum -y install sysstat
```

Set the storage items (data, log, journal) to be owned by the user (`mongod`) and group (`mongod`) that MongoDB will be starting under:

```
$ sudo chown mongod:mongod /data
$ sudo chown mongod:mongod /log
$ sudo chown mongod:mongod /journal
```

Now edit the MongoDB configuration file and update the following parameters

```
$ sudo nano /etc/mongod.conf
...
logpath=/log/mongod.log
logappend=true
fork=true
dbpath=/data
...
```

### Starting MongoDB

Set the MongoDB service to start at boot and activate it:

```
$ sudo chkconfig mongod on
$ sudo /etc/init.d/mongod start
```

When starting for the first time, it will take a couple of minutes for MongoDB to start, setup it's storage and become available. Once it is, you should be able to connect to it from within your instance:

```
$ mongo
MongoDB shell version: 2.0.4
connecting to: test
>
```
Just to confirm the system is working correctly, try creating a test database, test collection and save a document:

```bash
> use testdb
switched to db testdb
> db.createCollection("testCollection")
{ "ok" : 1 }
> db.testCollection.save({"name":"bob"})
> db.testCollection.find()
{ "_id" : ObjectId("4edfda1c86176ab8e27ee976"), "name" : "bob" }
```

Now that we've got a single node up and running with EBS backed RAID storage, let's move on and create a multi-node replica set.

**Deploying a Multi-node Replica Set**

**Replica Set Background**

Replica sets are a form of asynchronous master/slave replication, adding automatic failover and automatic recovery of member nodes. A replica set consists of two or more nodes that are copies of each other (i.e.: replicas). Refer to the MongoDB Replica Set documentation for more information.

**Create and Configure Instances**

For this guide, we'll set up a three node replica set. To set up each node use the instructions from Deploying a Single Node above. Once that's completed, we'll update the configurations for each node and get the replica set started.

First we'll need to edit the MongoDB configuration and update the `replSet` parameter:

```bash
$ sudo nano /etc/mongod.conf
...
replSet=exampleReplicaSetName
...
```

Save the configuration file and restart `mongod`:

```bash
$ sudo /etc/init.d/mongod restart
```

**Configure Replica Set**

Once MongoDB has started and is running on each node, we'll need to connect to the desired primary node, initiate the replica set and add the other nodes. First connect to the desired primary via SSH and then start mongo to initiate the set:

```bash
$ mongo
MongoDB shell version: 2.0.4
connecting to: test
> rs.initiate()
{ "info2" : "no configuration explicitly specified -- making one",
  "me" : "ip-10-127-127-91:27017",
  "info" : "Config now saved locally. Should come online in about a minute.",
  "ok" : 1
}
```

Next, add the other nodes to the replica set:
The 3 node replica set is now configured. You can confirm the setup by checking the health of the replica set:

```
PRIMARY> rs.status()

{  
    "set" : "exampleReplicaSetName",
    "date" : "Tue Dec 06 2011 11:39:08 GMT-0500 (CDT)",
    "myState" : 1,
    "members" : [  
        {  
            "name" : "ip-10-127-127-91:27017",
            "self" : true,
        },
        {  
            "name" : "ec2-107-21-46-145.compute-1.amazonaws.com:27017",
            "health" : 1,
            "uptime" : 101,
            "lastHeartbeat" : "Tue Dec 06 2011 11:39:07 GMT-0500",
        },
        {  
            "health" : 1,
            "uptime" : 107,
            "lastHeartbeat" : "Tue Dec 06 2011 11:39:07 GMT-0500",
        }
    ],
    "ok" : 1
}
```

What we've completed here is a simple replica set; there are additional configurations out there that may make more sense for your deployment, refer to the MongoDB documentation for more information. If you intend to use your replica set to help scale read capacity, you'll also need to update your application's code and add the appropriate `slaveOk=true` where necessary so that read results can be returned from additional nodes more quickly.

**Deploying a Sharded Configuration**

MongoDB scales horizontally via a partitioned data approach known as sharding. MongoDB provides the ability to automatically balance and distribute data across multiple partitions to support write scalability. For more information, refer to the MongoDB sharding docs.

**Simple Sharding Architecture**

To build our simple sharded configuration, we'll be building upon the replica set steps we just worked on. To get started you'll need to create two additional replica set configurations, just the same from above. When configuring each server instance we'll set the `shardsvr` parameter inside the `mongod` configuration file. Next we'll take one node from each replica set and set it to run as a config server as well. The config server maintains metadata about the sharded data storage cluster. Finally, we'll add instances for the `mongos` router, which handles routing requests from your app to the correct shard. The recommended approach is to run this component on your application servers. The following image shows a recommended topology for use with sharding:
Use the instructions from Deploying a Single Node above to create the required nodes for each replica set (3 instances per set, for a total of 9 instances). Now start configuring the replica set but before saving /etc/mongod.conf, add this parameter:

```bash
shardsvr = true
```

Save the configuration file and restart mongod:

```bash
$ sudo /etc/init.d/mongod restart
```

Once /etc/mongod.conf has been updated, initiate the replica set and add the members as described in Configure Replica Set. Once that's complete, choose one instance from each replica set and start an additional mongod process those instances, this time as the config server component:

```bash
$ mongod --configsvr
```

Now that we've got N config servers running (where N is the number of running replica sets) we can set up the request router mongos. This process typically runs on your application servers and handles routing database requests from your app to the correct database shard. Assuming you already have your application configured and deployed, use ssh to connect to each instance and install MongoDB using the steps from Install and Configure MongoDB.

Before we continue, it is important to consider the role DNS plays in a sharding setup. Generally we recommend using DNS hostnames for configuring replica sets, which Amazon handles appropriately, as opposed to using specific IP addresses. Essentially, AWS knows the mapping between public and private addresses and hostnames and manages inter-region domain name resolution. Therefore, by using the public DNS name for our servers we can ensure that whether our servers are in a single region or across multiple regions, AWS will correctly route our requests. When it comes to setting up sharding, we recommend an additional step of using DNS aliases for the instances that will be acting as config servers. The routers must know the hostnames of the config servers so by using DNS aliases we gain additional flexibility if config servers ever need to change. All it takes is pointing the DNS alias to another instance and no additional update to the router configuration is needed. For more information on this topic, refer to docs on changing config servers.

Once the DNS settings have taken effect, we can proceed with the mongos setup. Go back to the command line on each of the instances you'll be using for mongos and start the service and point it to the instances running the config server using their DNS aliases (ex: alias1.yourdomain.com, alias2.yourdomain.com and alias3.yourdomain.com) along with the config server port 27019:

```bash
$ mongos --configdb
```

With the mongos routers running, we can now complete the setup for the sharding architecture. The last step is to add the previously created replica sets to the overall system. Choose one of the instances that is running mongos, start the mongo client using the hostname and port (27017) and connect to the admin database. You'll need to have the name for each replica set (ex: replicaSetName1) and the hostnames for each member of the set (e.g: replicaSetHost1)
The `addShard` command will need to be repeated for each replica set that is part of the sharded setup:

```
> db.adminCommand({addShard:
  "replicaSetName2/replicaSetHost4:27018,replicaSetHost5:27018,replicaSetHost6:27018"})
> db.adminCommand({addShard:
  "replicaSetName3/replicaSetHost7:27018,replicaSetHost8:27018,replicaSetHost9:27018"})
```

Once these steps have been completed, you’ll have a simple sharded configuration. The architecture we used includes 3 database shards for write scalability and three replicas within each shard for read scalability and failover. This type of setup deployed across multiple regions (ex: one node from each replica located in `us-west-1`) would also provide some degree of disaster recovery as well.

In order to utilize this newly created configuration, you’ll need to specify which databases and which collections are to be sharded. See [Enabling Sharding on a Database](#) and [Sharding a Collection](#) for more information.

### Backup and Restore

There are several ways to backup your data when using AWS, refer to the [EC2 Backup & Restore](#) guide for more information.

#### EC2 Backup & Restore

**Overview**

This article describes how to backup, verify & restore a MongoDB running on EC2 using EBS Snapshots.

**Backup**

How you backup MongoDB will depend on whether you are using the `--journal` option in 1.8 (or above) or not.

**Backup with --journal**

The journal file allows for roll forward recovery. The journal files are located in the `dbpath` directory so will be snapshotted at the same time as the database files.

If the `dbpath` is mapped to a single EBS volume then proceed to the [Backup the Database Files](#) section.

If you `dbpath` is mapped to multiple EBS volumes, in order to guarantee the stability of the file-system then you will need to [Flush and Lock the Database](#) section.

Note that snapshotting with the journal is only possible if the journal resides on the same volume as the data files, so that one snapshot operation captures the journal state and data file state atomically.

**Backup without --journal**

In order to correctly backup a MongoDB, you need to ensure that writes are suspended to the file-system before you backup the file-system. If writes are not suspended then the backup may contain partially written or data which may fail to restore correctly.

Backing up MongoDB is simple to achieve using the `fsync + lock` command. If the file-system is being used only by the database, then you can then use the snapshot facility of EBS volumes to create a backup. If you are using the volume for any other application then you will need to ensure that the file-system is frozen as well (e.g. on XFS file-system use `xfs_freeze`) before you initiate the EBS snapshot. The overall process looks like:
Flush and Lock the database

Writes have to be suspended to the file-system in order to make a stable copy of the database files. This can be achieved through the MongoDB shell using the `fsync + lock` command.

```javascript
mongo shell> use admin
mongo shell> db.runCommand({fsync:1,lock:1});
{
  "info": "now locked against writes, use db.$cmd.sys.unlock.findOne() to unlock",
  "ok": 1
}
```

During the time the database is locked, any write requests that this database receives will be rejected. Any application code will need to deal with these errors appropriately.

Backup the database files

There are several ways to create an EBS Snapshot, for example with Elastic Fox or the AWS Command line. The following examples use the AWS command line tool.

Find the EBS volumes associated with the MongoDB

If the mapping of EBS Block devices to the MongoDB data volumes is already known, then this step can be skipped. The example below shows how to determine the mapping for an LVM volume, please confirm with your System Administrator how the original system was setup if you are unclear.

Find the EBS block devices associated with the running instance

```bash
shell> ec2-describe-instances
RESERVATION r-eb09aa81 289727918005 tokyo, default
INSTANCE i-78803e15 ami-4b4ba522 ec2-50-16-30-250.compute-1.amazonaws.com
ip-10-204-215-62.ec2.internal running scaleout 0 ml.large 2010-11-04T02:15:34+0000 us-east-1a
  aki-0b4aa462 monitoring-disabled 50.16.30.250 10.204.215.62 ebs paravirtual
BLOCKDEVICE /dev/sda1 vol-6ce9f105 2010-11-04T02:15:43.000Z
BLOCKDEVICE /dev/sdf vol-96e8f0ff 2010-11-04T02:15:43.000Z
BLOCKDEVICE /dev/sdh vol-90e8f0f9 2010-11-04T02:15:43.000Z
BLOCKDEVICE /dev/sdg vol-68e9f101 2010-11-04T02:15:43.000Z
BLOCKDEVICE /dev/sdi vol-94e8f0fd 2010-11-04T02:15:43.000Z
```

As can be seen in this example, there are a number of block devices associated with this instance. We have to determine which volumes make up the file-system we need to snapshot.
**Determining how the dbpath is mapped to the file-system**

Log onto the running MongoDB instance in EC2. To determine where the database file are located, either look at the startup parameters for the mongod process or if mongod is running, then you can examine the running process.

```
root> ps -ef | grep mongo
ubuntu   10542     1  0 02:17 ?     00:00:00 /var/opt/mongodb/current/bin/mongod --port 27000 --shardsvr --dbpath /var/lib/mongodb/tokyo0 --fork --logpath /var/opt/mongodb/log/server.log --logappend --rest
```

dbpath is set to `/var/lib/mongodb/tokyo0` in this example.

**Mapping the dbpath to the physical devices**

Using the `df` command, determine what the `--dbpath` directory is mapped to

```
root> df /var/lib/mongodb/tokyo0
Filesystem        1K-blocks    Used Available Use% Mounted on
/dev/mapper/data_vg-data_vol 104802308  4320 104797988   1% /var/lib/mongodb
```

Next determine the logical volume associated with this device, in the example above `/dev/mapper/data_vg-data_vol`

```
root> lvdisplay /dev/mapper/data_vg-data_vol
--- Logical volume ---
 LV Name                /dev/data_vg/data_vol
 VG Name                data_vg
 LV UUID                fixOyX-6AIw-PnBA-i2bp-ovUc-u9uu-TGvjl
 LV Write Access        read/write
 LV Status              available
 # open                 1
 LV Size                100.00 GiB
...
```

This output indicates the volume group associated with this logical volume, in this example `data_vg`. Next determine how this maps to the physical volume.

```
root> pvscan
PV /dev/md0 VG data_vg lvm2 [100.00 GiB / 0 free]
Total: 1 [100.00 GiB] / in use: 1 [100.00 GiB] / in no VG: 0 [0 ]
```

From the physical volume, determine the associated physical devices, in this example `/dev/md0`.

```
root> mdadm --detail /dev/md0
/dev/md0:
  Version : 00.90
  Creation Time : Thu Nov  4 02:17:11 2010
  Raid Level : raid10
  Array Size : 104857472 (100.00 GiB 107.37 GB)
  Used Dev Size : 52428736 (50.00 GiB 53.69 GB)
  Raid Devices : 4
  ... single
  UUID : 07552c4d:6c11c875:e5a1de64:a9c2f2fc (local to host ip-10-204-215-62)
  Events : 0.19

  Number Major Minor  RaidDevice State
    0     8     80 0 active sync /dev/sdf
    1     8     96 1 active sync /dev/sdg
    2     8    112 2 active sync /dev/sdh
    3     8    128 3 active sync /dev/sdi
```

We can see that block devices /dev/sdf through /dev/sdi make up this physical devices. Each of these volumes will need to be snapped in order to complete the backup of the file-system.
Create the EBS Snapshot

Create the snapshot for each device. Using the `ec2-create-snapshot` command, use the Volume Id for the device listed by the `ec2-describe-instances` command.

```shell
shell> ec2-create-snapshot -d backup-20101103 vol-96e8f0ff
SNAPSHOT snap-417af82b vol-96e8f0ff pending 2010-11-04T05:57:29+0000 289727918005 50 backup-20101103
shell> ec2-create-snapshot -d backup-20101103 vol-90e8f0f9
SNAPSHOT snap-5b7af831 vol-90e8f0f9 pending 2010-11-04T05:57:35+0000 289727918005 50 backup-20101103
shell> ec2-create-snapshot -d backup-20101103 vol-68e9f101
SNAPSHOT snap-577af83d vol-68e9f101 pending 2010-11-04T05:57:42+0000 289727918005 50 backup-20101103
shell> ec2-create-snapshot -d backup-20101103 vol-94e8f0fd
SNAPSHOT snap-2d7af847 vol-94e8f0fd pending 2010-11-04T05:57:49+0000 289727918005 50 backup-20101103
```

Unlock the database

After the snapshots have been created, the database can be unlocked. After this command has been executed the database will be available to process write requests.

```mongo shell
mongo shell> db.$cmd.sys.unlock.findOne();
{ "ok" : 1, "info" : "unlock requested" }
```

Verifying a backup

In order to verify the backup, the following steps need to be completed:

- Check the status of the snapshot to ensure that they are "completed"
- Create new volumes based on the snapshots and mount the new volumes
- Run mongod and verify the collections

![Diagram](attachment:image.png)

Typically, the verification will be performed on another machine so that you do not burden your production systems with the additional CPU and I/O load of the verification processing.

Describe the snapshots

Using the `ec2 describe-snapshots` command, find the snapshots that make up the backup. Using a filter on the `description` field, snapshots associated with the given backup are easily found. The search text used should match the text used in the `-d` flag passed to `ec2-create-snapshot` command when the backup was made.
Create new volumes based on the snapshots

Using the `ec2-create-volume` command, create new volumes based on each of the snapshots that make up the backup.

```
backup shell> ec2-create-volume --availability-zone us-east-1a --snapshot snap-2d7af847
VOLUME vol-06aab26f 50 snap-2d7af847 us-east-1a creating 2010-11-04T06:44:27+0000
backup shell> ec2-create-volume --availability-zone us-east-1a --snapshot snap-417af82b
VOLUME vol-1caab275 50 snap-417af82b us-east-1a creating 2010-11-04T06:44:38+0000
backup shell> ec2-create-volume --availability-zone us-east-1a --snapshot snap-577af83d
VOLUME vol-12aab27b 50 snap-577af83d us-east-1a creating 2010-11-04T06:44:52+0000
backup shell> ec2-create-volume --availability-zone us-east-1a --snapshot snap-5b7af831
VOLUME vol-caaab2a3 50 snap-5b7af831 us-east-1a creating 2010-11-04T06:45:18+0000
```

Attach the new volumes to the instance

Using the `ec2-attach-volume` command, attach each volume to the instance where the backup will be verified.

```
backup shell> ec2-attach-volume --instance i-cad26ba7 --device /dev/sdp vol-06aab26f
ATTACHMENT vol-06aab26f i-cad26ba7 /dev/sdp attaching 2010-11-04T06:49:32+0000
backup shell> ec2-attach-volume --instance i-cad26ba7 --device /dev/sdq vol-1caab275
ATTACHMENT vol-1caab275 i-cad26ba7 /dev/sdq attaching 2010-11-04T06:49:58+0000
backup shell> ec2-attach-volume --instance i-cad26ba7 --device /dev/sdr vol-12aab27b
ATTACHMENT vol-12aab27b i-cad26ba7 /dev/sdr attaching 2010-11-04T06:50:13+0000
backup shell> ec2-attach-volume --instance i-cad26ba7 --device /dev/sds vol-caaab2a3
ATTACHMENT vol-caaab2a3 i-cad26ba7 /dev/sds attaching 2010-11-04T06:50:25+0000
```

Mount the volumes groups etc.

Make the file-system visible on the host O/S. This will vary by the Logical Volume Manager, file-system etc. that you are using. The example below shows how to perform this for LVM, please confirm with your System Administrator on how the original system was setup if you are unclear.

Assemble the device from the physical devices. The UUID for the device will be the same as the original UUID that the backup was made from, and can be obtained using the `mdadm` command.

```
backup shell> mdadm --assemble --auto-update-homehost -u 07552c4d:6c11c875:e5a1de64:a9c2f2fc
--no-degraded /dev/md0
mdadm: /dev/md0 has been started with 4 drives.
```

You can confirm that the physical volumes and volume groups appear correctly to the O/S by executing the following:

```
backup shell> pvscan
PV /dev/md0  VG data_vg  lvm2 [100.00 GiB / 0 free]
Total: 1 [100.00 GiB] / in use: 1 [100.00 GiB] / in no VG: 0 [0 ]
```

Create the mount point and mount the file-system:
Startup the database

After the file-system has been mounted, MongoDB can be started. Ensure that the owner of the files is set to the correct user & group. Since the backup was made with the database running, the lock file will need to be removed in order to start the database.

```
backup shell> chown -R mongodb /var/lib/mongodb/toyko0
backup shell> rm /var/lib/mongodb/toyko0/mongod.lock
backup shell> mongod --dbpath /var/lib/mongodb/toyko0
```

Verify the collections

Each collection can be verified in order to ensure that it valid and does not contain any invalid BSON objects.

```
mongo shell> db.blogs.validate({full: true})
```

Validate Command

Restore

Restore uses the same basic steps as the verification process.

1. `db.shutdownServer()`
2. `ec2-create-volume` `ec2-attach-volume`
3. `mount file-system`
4. `mongod`

After the file-system is mounted you can decide to

- Copy the database files from the backup into the current database directory
- Startup mongod from the new mount point, specifying the new mount point in the --dbpath argument

After the database is started, it will be ready to transact. It will be at the specific point in time from the backup, so if it is part of a master/slave or replica set relationship, then the instance will need to synchronize itself to get itself back up to date.

dotCloud
Running MongoDB on dotCloud

MongoDB can run on dotCloud. It supports replica sets, and has alpha support for sharding.

The whole point of dotCloud is to run your apps and your databases in the same place, to optimize for latency and reliability. However, you can also deploy MongoDB on dotCloud and use it to power an app running anywhere else.

If you don't have a dotCloud account yet...

Well, what are you waiting for? 😊

Go ahead and create one (it's free!) and install the CLI:

```
sudo easy_install pip ; sudo pip install dotcloud
```

If you need help to get the CLI running, check the dotCloud install docs and don't hesitate to ask for help.

With a dotCloud account

The following snippet will deploy MongoDB on dotCloud for you in no time:

```
mkdir mongodb-on-dotcloud
cat >mongodb-on-dotcloud/dotcloud.yml <<EOF
db:
  type: mongodb
EOF
dotcloud push mongorocks mongodb-on-dotcloud
dotcloud info mongorocks.db
```

The last command will show you the host, port, and credentials to be used to connect to your database.

Scaling

Assuming you followed the instructions of the previous section, if you want to get a replica sets of 3 servers:

```
dotcloud scale mongorocks db=3
```

Advanced use

If you want to have a closer look at your MongoDB server, nothing beats SSH access:

```
dotcloud ssh mongorocks.db
```

Moar docs

- dotCloud documentation for the MongoDB service
- generic introduction to dotCloud (in case you want to run not only MongoDB, but also Node.js, Python, Ruby, Perl, Java, RabbitMQ, Redis, MySQL, PostgreSQL, CouchDB, Riak, Erlang, or something else, on dotCloud)

Ready-to-use apps

All you need to do to run them is a git clone and a dotcloud push:

- Django setup using MongoDB to store objects
- MongoDB + Node.js sample app
Getting help

dotCloud has a Q&A site, and the dotCloud team can be reached through the FreeNode IRC network on #dotcloud.

Joyent

For the quickest start, you can use the Joyent SmartMachine for MongoDB Appliance

For installing MongoDB on a Joyent Node Smart Machine, see this article

The prebuilt MongoDB Solaris 64 binaries work with Joyent accelerators.

Some newer gcc libraries are required to run -- see sample setup session below.

```bash
$ # assuming a 64 bit accelerator
$ /usr/bin/isainfo -kv
64-bit amd64 kernel modules

$ # get mongodb
$ # note this is 'latest' you may want a different version
$ curl -O http://downloads.mongodb.org/sunos5/mongodb-sunos5-x86_64-latest.tgz
$ gzip -d mongodb-sunos5-x86_64-latest.tgz
$ tar -xf mongodb-sunos5-x86_64-latest.tar
$ mv "mongodb-sunos5-x86_64-2009-10-26" mongo

$ cd mongo

$ # get extra libraries we need (else you will get a libstdc++.so.6 dependency issue)
$ gzip -d mongo-extra-64.tgz
$ tar -xf mongo-extra-64.tar
$ # just as an example - you will really probably want to put these somewhere better:
$ export LD_LIBRARY_PATH=mongo-extra-64
$ bin/mongod --help
```

MongoDB on Azure - Overview

Overview

MongoDB on Azure brings the power of the leading NoSQL database to Microsoft’s flexible, open, and scalable cloud.

Windows Azure is the cloud services operating system that serves as the development, service hosting, and service management environment for the Azure Services Platform. Windows Azure provides developers on-demand compute & storage to create, host and manage scalable and available web applications through Microsoft data centers.

Together, MongoDB and Azure provide customers the tools to build limitlessly scalable applications in the cloud.

Deployment Options

Users interested in deploying MongoDB on Azure can do so using Azure Worker Roles (Azure Platform-as-a-Service) or Azure VM (Azure Infrastructure-as-a-Service). For further information, please see the relevant documentation:

**Azure Worker Roles (Platform-as-a-Service)**

- Introduction
- Configuration
- Deployment
- Building a MongoDB Azure application

**Azure VM (Infrastructure-as-a-Service)**

- Introduction
- Windows Installer
- Linux Tutorial
Users deploying MongoDB on Azure may be interested in the following presentations, as well:

MongoDB on Azure VM

Windows Azure VMs allow you to deploy both Windows and Linux virtual machines to the Windows Azure cloud service. These VMs are similar to local instances or other IaaS services and hence can be used to run MongoDB instances. Currently Windows Azure VMs are in preview and you need to sign up for the preview to use the feature and deploy MongoDB to it.

- Signing Up

**Signing Up**

Sign up for ‘Virtual Machines and Virtual Networks’ preview feature from the new Azure portal*

In the ‘Preview’ portal, go to Account->Preview Features.

![Sign up for the “Virtual Machines and Virtual Networks”](image)
MongoDB on Azure VM - Linux Tutorial

In this tutorial, you will learn to deploy a MongoDB replica set to CentOS VMs on Windows Azure and access it from outside Azure. The following are the tasks to achieve this:

1. Sign up for the feature on the Azure portal
2. Set up affinity group
3. Create and set up the virtual machines
4. Install and run MongoDB
5. Configure the replica set

Signing Up

Sign up for ‘Virtual Machines and Virtual Networks’ preview feature from the new Azure portal*. More information can be found [here](#).

Set Up Affinity Group

The affinity group needs to be set up from the old portal.

1. If in the new Azure Management preview portal, click your user name in the top right of the screen, then ‘Previous Portal’ to switch to the old portal.

2. Once in the old portal, click ‘Hosted Services, Storage Accounts & CDN’
3. Select ‘Affinity Groups’ and then ‘New Affinity Group’
4. In the “Create a New Affinity Group” dialog, enter an affinity group name such as “mongoaffinitygroup” and choose a location
   • Choose one of the newer Azure data centers such as “West US,” “East US” or “West Europe”
Create and Set Up the Virtual Machines

To create a 3-node MongoDB replica set you will be creating 3 VM instances. For this step, log in to the new preview portal, or from the old portal, click 'Visit the Previous Portal' at the bottom of the page

Create Instances

Instance 1

1. In the portal, click New->Virtual Machine->From Gallery

2. On the VM OS Selection page, choose 'OpenLogic CentOS 6.2' and click the next arrow to continue
3. On the VM Configuration page, specify values for the parameters
   - Virtual Machine Name - "mongodbrs1"
   - New User Name – "mongouser." This user will be added to the ‘sudoers’ list file
   - New Password box – type a strong password that conforms to the Azure specifications
   - Retype the password to confirm
   - Size – Choose appropriate size from drop down list. For anything but small test instances, choose a size larger than Medium
   - Leave ‘Upload SSH key for Authentication’ unchecked

   Click the next arrow to continue

4. On the VM Mode page, specify values for the required parameters
   - Select ‘Standalone Virtual Machine’
   - DNS – a valid DNS prefix e.g., "mongodbs"
   - Storage Account box – choose ‘Use Automatically Generated Storage Account’
   - In the ‘Region/Affinity Group/Virtual Network’ box, select the affinity group created previously “mongoaffinitygroup”
Click the check mark to create the VM instance

5. On the VM Options page select 'None for Availability Set'

6. Click the check mark to create the VM instance
Instance 2

A similar process to creating instance 1.

1. In the portal, click New->Virtual Machine->From Gallery
2. On the VM OS Selection page, choose ‘OpenLogic CentOS 6.2’ and click the next arrow to continue
3. On the VM Configuration page, specify values for the parameters
   - Virtual Machine Name - “mongodbrs2”
   - New User Name – “mongouser.” This user will be added to the ‘sudoers’ list file
   - New Password box – type a strong password that conforms to the Azure specifications
   - Retype the password to confirm
   - Size – Choose the same size as instance 1
   - Leave ‘Upload SSH key for Authentication’ unchecked
   
   Click the next arrow to continue
4. On the VM Mode page, specify values for the required parameters
   - Select ‘Connect to Existing Virtual Machine’
   - In the dropdown choose the host created in instance 1, in this case ‘mongodbrs1’
   - Storage Account box – choose ‘Use Automatically Generated Storage Account’
   - The ‘Region/Affinity Group/Virtual Network’ box should be automatically set to “mongoaffinitygroup”
   
   Click next arrow to continue

Instance 3

A similar process for creating instance 2. Choose ‘mongodbrs3’ to be the Virtual Machine Name in step 3.

Configure Endpoints

Once the virtual machines are connected you need to configure the endpoints to:

- Allow remote connection
- Allow mongo traffic

Instance 1:

1. In the management portal, click virtual machines and click the name of instance 1, ‘mongodbrs1’
2. Now click on endpoints
3. The ssh endpoint should be automatically created. For this endpoint ensure the following are set
   - Protocol – tcp
   - Public Port – 22
   - Private Port – 22
   - Load Balanced – No
4. Create a new endpoint for MongoDB by clicking on ‘Add Endpoint’ at the bottom of the screen
5. Ensure ‘Add endpoint’ is selected and click the right arrow to go to the next screen

6. Specify the endpoint details as below:
   - Name : MongoDB-Port
   - Protocol : TCP
   - Public Port : 27018
   - Private Port : 27018
   - Click on check mark to create endpoint
The instance now should have 2 endpoints, 1 for SSH and 1 for MongoDB

Instance 2:

We need to configure the endpoints for instance 2 similar to instance 1:

1. In the management portal, click 'virtual machines' and click the name of instance 2
2. Now click on 'endpoints'
3. The ssh endpoint should be automatically created. Ensure that:
   - Name – SSH
   - Protocol – TCP
   - Private Port – 22
   - Load Balanced – No
4. Now click on Edit Endpoint at the bottom of the screen and set ‘Public Port’ to 23. Click on the ‘check mark’ to update
5. Create a new endpoint for MongoDB by clicking on ‘Add Endpoint’ at the bottom of the screen
6. Ensure ‘Add Endpoint’ is selected and click the right arrow to go to the next screen
7. Specify the endpoint details as below:
   - Name : MongoDB-Port
   - Protocol : TCP
   - Public Port : 27019
   - Private Port : 27019
   - Click on check mark to create endpoint

The instance now should have 2 endpoints, 1 for SSH and 1 for MongoDB
Instance 3:

Create endpoints for instance 3 similar to instance 2 with the following changes:

1. In step 4, set public port to 24
2. In step 7, set public and private ports to be 27020

The instance now should have 2 endpoints, 1 for SSH and 1 for MongoDB

Update OS

Use this optional step to update the operating system on each of your VM instances. Once the machine endpoints have been configured above, you need to log into the machines to update them. More information on this can be found at ‘How to Log on to a Virtual Machine Running Linux’

Use the username and password you used when creating the virtual machine instances.

Once you are connected to the machine, update the operating system by running: `sudo yum update` and following the prompts. This could take some time.

Note: When connecting to instances 2 and 3, remember to use ports 23 and 24 and not the default ssh port of 22.

Set up disks
Once the instances are updated, you can then attach a data disk to each of the instances. The data disks will be storing the actual mongodb data as part of --dbpath. More information on Azure data disks can be found at Data Disk Concepts.

To set up the data disk follow the steps outlined below for each of the instances you created:

1. Attach an empty disk to the instance as described in How to: Attach an empty disk
   a. Create a data disk of at least 10 GB
2. Now initialize the data disk by following the steps described at How to: Initialize a new data disk in Linux
3. Also once mounted, create a mongodb data directory by:
   a. Log on onto the instance
   b. Then run `sudo chown id -u /mnt/datadrive/` to make the mongouser the owner of the data directory
   c. Run the following command: `mkdir -p /mnt/datadrive/data`

Install and Run MongoDB

As part of this step, you will be using the official 10gen supplied packages to install, configure and run MongoDB as a service using YUM. You want to install as a service since this would ensure that mongod is started on machine restart also. More information can be found at Install MongoDB on RedHat Enterprise, CentOS, or Fedora Linux doc page.

Install MongoDB

Repeat the following steps on each instance:

1. Log onto the instance
2. Create a `/etc/yum.repos.d/10gen.repo` file to hold information about your repository using your favorite editor as sudo. Place the following configuration in `/etc/yum.repos.d/10gen.repo` file:
   ```
   [10gen]
   name=10gen Repository
   baseurl=http://downloads-distro.mongodb.org/repo/redhat/os/x86_64
   gpgcheck=0
   enabled=1
   ```
3. After saving the new .repo file, issue the following command to update the local package database: `sudo yum update`
4. Issue the following command (as root or with sudo) to install the latest stable version of MongoDB and the associated tools: `sudo yum install mongo-10gen mongo-10gen-server`

5. When this command completes, you have successfully installed MongoDB.
Configure MongoDB

The packages installed in the previous step configure MongoDB using the /etc/mongod.conf file in conjunction with the control script. You can find the init script at /etc/rc.d/init.d/mongod. As part of this step you will edit the mongod.conf file to set the appropriate parameters. If the parameters are commented, make sure to uncomment them.

Instance 1

1. Connect to the instance using ssh or PuTTY
2. As sudo, edit /etc/mongod.conf to set the following parameters:
   - port = 27018
   - dbpath = /mnt/datadrive/data
   - logpath = /mnt/datadrive/mongod.log
   - replSet = mongors
3. Save the config file

Instance 2

1. Connect to the instance using ssh or PuTTY, remembering the SSH port for this node has been changed from the default of 22
2. As sudo, edit /etc/mongod.conf to set the following parameter:
   - port = 27019
   - dbpath = /mnt/datadrive/data
   - logpath = /mnt/datadrive/mongod.log
   - replSet = mongors
3. Save the config file

Instance 3

1. Connect to the instance using ssh or PuTTY, remembering the SSH port for this node has been changed from the default of 22
2. As sudo, edit /etc/mongod.conf to set the following parameter:
   - port = 27020
   - dbpath = /mnt/datadrive/data
   - logpath = /mnt/datadrive/mongod.log
   - replSet = mongors
3. Save the config file

Start MongoDB

Once the configuration files have been edited, start the database process mongod on each instance by:

1. Log on onto the instance
2. Run the following command to start the process:
   
   mongod --config /etc/mongod.conf
3. This should start the mongod process
4. Verify that mongod start by tailing the log file using the command
   `tail --f /mnt/datadrive/mongod.log`

5. The ‘waiting for connections’ message in the log file indicates mongod is up and running and waiting for client connections. This may take a while as mongod preallocates its journal files

---

Configure the Replica Set

At this point in time, you should have mongod running on all 3 of your instances. You can now configure the 3 instances as a replica set by connecting to 1 of the 3 instances from within Azure or from outside.

Connect to the running mongod process using the mongo shell:

1. If connected to the VM instance type the following command where port is 27018 for instance 1, 27019 for instance 2 and 27020 for instance 3: `mongo --port <port number>`
2. If connecting to the mongod process in Azure from your local machine use the following command: `mongo --host mongodbrs.cloudapp.net --port <port number>`
3. In the mongo shell type the following:

   ```
   > conf = {
   _id = "mongors",
   members : [
      (_id:0, host="mongodbrs.cloudapp.net:27018"),
      (_id:1, host="mongodbrs.cloudapp.net:27019"),
      (_id:2, host="mongodbrs.cloudapp.net:27020"))
   >rs.initiate(conf)
   ```
3. This will start the initialization of the mongod replica set

4. Type the command `rs.status()` to check the status of the replica set. Upon successful initialization, you should see 1 of the 3 instances being the ‘Primary’ of the set and the other 2 being the ‘Secondaries’

5. You have now successfully initiated the replica set

**Summary**

In this tutorial you have learned how to create a set of CentOS virtual machines on Windows Azure, deploy MongoDB to them and create a replica set out of them. You can access this set from anywhere using the connection string `mongodb://mongodbrs.cloudapp.net:27018, mongodbrs.cloudapp.net:27019, mongodbrs.cloudapp.net:27020/?replicaSet=mongors`. 
More information on MongoDB can be found at http://docs.mongodb.org/manual/.

To create and deploy a replica set to Windows Virtual Machines on Azure you can use the MongoDB Installer for Windows Azure.

**MongoDB on Azure VM - Windows Installer**

The MongoDB Installer for Windows Azure is a tool that can be used to provision a MongoDB replica set cluster into Window Azure VM instances.

The following are the steps to deploy a replica set using the tool:

1. Install the MongoDB Installer for Windows Azure
2. Download publish settings file
3. Run the MongoDB Installer

- Prerequisites
- Install and Deployment
  - Install the tool.
  - Download your publish settings file:
  - Run the MongoDB Installer
- Troubleshooting

**Prerequisites**

- You need to be signed for Windows Azure VM Preview
- Windows versions: any 32-bit or 64-bit Windows 7 version
- Accounts: you must have administrator access to run the setup program and installer

**Install and Deployment**

Install the tool.

If you haven't done so already, you can download the MongoDB Installer for Windows Azure here.
Double click on the msi and accept the license agreement to complete the installation.

Download your publish settings file:

The publish settings file is an xml file containing information about your subscription. This information is used by the actual script to create the VM instances in your account. To download the publish settings file, use the downloader start menu item:
Sign in with your Windows Live ID credentials when prompted. Remember the path to where the file was downloaded.

**Run the MongoDB Installer**

The MongoDB Installer for Azure is a powershell script. To install and configure your replica launch the installer as an Administrator.

Right click on the above start menu item and choose Run as administrator. This will open a power shell window where you can run the script to configure MongoDB on Azure VMs. You would deploy as:

```
..\deploy-mongo.ps1 <node-count> <dns-prefix> <image-name> <password> <location>
<pub-settings-file-path> [replica-set-name]
```

- **node-count** - The number of instances required in the replica set. Setting this to 1 results in a stand alone instance being deployed and not a replica set.

- **dns-prefix** - The DNS prefix that will be used in the FQDN of an instance. For example, if you specify a DNS prefix of myreplicaset, the URL is http://myreplicaset.cloudapp.net. The DNS prefix is not case-sensitive.

- **image-name** - The name of the VHD image in your Windows Azure storage account that will be used to create the virtual machines for the replica set. There are two possibilities:
  - You can specify the name of an existing image that you've created, which must meet these criteria:
    - It is based on the Windows Server 2008 R2 operating system.
    - It has WinRM enabled with HTTP listener.
    - It is hosted in your storage account.
  - You can specify the name of a new image that the tool will create for you in your storage account. If the installer finds no existing image with the name you specified, it assumes that you want to create a new image and prompts you to confirm before proceeding. The new image will meet the requirements listed earlier for an existing image. Note that for this option, the name you provide cannot match any of the names of existing Windows Azure platform images.

- **password** - The password to the Administrator account on the provisioned virtual machines. The same password is used for all virtual machines (nodes) in the replica set, and the password must meet Windows password complexity requirements. You will use this password when you connect to the virtual machines via Remote Desktop Protocol (RDP) to perform system management and troubleshooting activities. Note that RDP is enabled on all virtual machines provisioned by the MongoDB Installer for Windows Azure.

- **location** - The Windows Azure data center location where your virtual machines will be provisioned. Note that data center locations are case sensitive. For example, you might use “North Central US” as a location. If you don’t know which locations are available for your Windows Azure subscription, you can use either of these methods to see a list of available locations:
  - Sign in to the management portal on https://windows.azure.com, click New Hosted Service, and then click Choose a Region to see a dropdown list of locations. Click Cancel when you’re done.
  - You can use the azure vm location list command to display a list of available locations. Note that the installer installs the command-line tools if they are missing; however, if you want to install them before you run the installer you can do so with the Windows PowerShell script *setup-iasstool.ps1.

- **pub-settings-file-path** - The path to the publish settings file you downloaded earlier.

- **replica-set-name** - This optional can be used to specify the name of your replica set. The default name is rs. This parameter is ignored if node-count is set to 1, because a single-node deployment is not a replica set.

**Troubleshooting**

Qn. Error with unauthorized during deployment as seen below:

```
error: The subscription is not authorized for this feature.
error: vm image create command failed
```
**Ans.** This usually indicates you do not have access to the VM preview program. Can you verify in the [new preview portal](#) that "Preview Features" shows account is active for Virtual machines and Virtual networks. If you have multiple accounts/subscriptions make sure you download the right pubsettings file.

**Qn.** I am seeing a timeout error from the installer

```plaintext
Error: connect ETIMEDOUT
```

**Ans.** This occasionally occurs due to connectivity issues with the Azure service management server or your actual deployed instances. At this point the work around is to retry. Working on making this more robust.

**Qn.** In spite of meeting the strong password requirements the installer fails in the password setting

**Ans.** Ensure you do not have a $ in the password as powershell is parsing it out as a parameter.

---

**MongoDB on Azure Worker Roles**

The MongoDB Worker Role is currently a preview release. Please provide feedback, [mongodb-dev](#), [mongodb-user](#) and IRC #mongodb are good places!

- Getting the package
- Components
- Initial Setup
- Deploying and Running
  - Running locally on compute/storage emulator
  - Deploying to Azure
- Additional Information
- FAQ/Troubleshooting
- Known issues/Where do I file bugs?

The MongoDB Worker Role project allows you to deploy and run a MongoDB replica set on Windows Azure. Replica set members are run as Azure worker role instances. MongoDB data files are stored in an Azure page blob mounted as a cloud drive. One can use any MongoDB driver to connect to the MongoDB server instance. The MongoDB .Net driver is included as part of the package.

**Getting the package**

The MongoDB Azure Worker Role is delivered as a Visual Studio 2010 solution with associated source files. The simplest way to get the package is by downloading it from [GitHub](#). It is recommended using the latest tagged version.

Alternatively, you can clone the repository run the following commands from a git bash shell:

```
$ cd <parentdirectory>
$ git config --global core.autocrlf true
$ git clone git@github.com:mongodb/mongo-azure.git
$ cd mongo-azure
$ git config core.autocrlf true
```

You must set the global setting for core.autocrlf to true before cloning the repository. After you clone the repository, we recommend you set the local setting for core.autocrlf to true (as shown above) so that future changes to the global setting for core.autocrlf do not affect this repository. If you then want to change your global setting for core.autocrlf to false run:

```
$ git config --global core.autocrlf false
```

**Components**

Once you have unzipped the package or cloned the repository, you will see the following directories:

- **Setup** - Contains a file called solutionsetup.cmd. Run this before opening the solution file.
- **src** - Contains all the project's source code.
- **src/SampleApplications** - Contains sample applications that you can use to demo MongoDB on Azure. See the listing for more info.
- **lib** - Library files. Includes the MongoDB .NET driver
- **Tools** - Contains miscellaneous tools for the project.

**Initial Setup**
We assume you’re running Windows x64 and Visual Studio. If not, install those first; Visual Studio 2010 or Visual Web Developer 2010 should work.

1. Install the latest Windows Azure SDK June 2012
2. Enable IIS on your local machine. This can be done by going to the “Turn Windows features on or off” control panel, under “Programs”. Check “Internet Information Services” and also check ASP.NET under World Wide Web Services|Application Development Features.
3. Clone the project.
4. Before opening either solution file, run Setup\solutionsetup.cmd.
4. Open the solution you want, set the “MongoDB.WindowsAzure.(Sample.)Deploy” project as the StartUp Project, and run it!

The setup script does the following:

- Creates the cloud configs for the 2 solutions
- Downloads the MongoDB binaries to lib\MongoDBBinaries.

32-bit note: The setup script downloads the 64-bit version of MongoDB by default. If you are developing with 32-bit Windows, you will need to download the latest 32-bit MongoDB binaries and place them in lib\MongoDBBinaries yourself. Do this after running solutionsetup.cmd so it won’t overwrite your work.

The prerequisites can be found in the Github readme

Once these are installed, you can open either solution MongoDB.WindowsAzure.sln for just the replica set and the monitoring application; MongoDB.WindowsAzure.Sample.sln for the replica set, monitoring application and a sample IIS app, MvcMovie, to test it.

**Deploying and Running**

**Running locally on compute/storage emulator**

The following instructions are for running the sample application.

To start, you can test out your setup locally on your development machine. The default configuration has 3 replica set members running on ports 27017, 27018 and 27019 with a replica set name of 'rs'.

In Visual Studio, run the solution using F5 or Debug->Start Debugging. This will start up the replica set, the monitoring application and the MvcMovie sample application (if you are in the sample solution).

You can verify this by using the monitoring application or MvcMovie sample application in the browser or by running mongo.exe against the running instances.

**Deploying to Azure**

Once you have the application running locally, you can deploy the sample app solution to Windows Azure. Note You cannot execute locally (on the compute emulator) with data stored in Blob store. This is due to the use of Windows Azure Drive which requires both compute and storage are in the same location.

- Detailed configuration options are outlined [here](#)
- Step-by-step deployment instructions are [here](#)

**Additional Information**

The MongoDB Worker Role runs mongod.exe with the following options:

```
--dbpath --port --logpath --journal --nohttpinterface --logappend --replSet
```

MongoDB creates the following containers and blobs on Azure storage:

- Mongo Data Blob Container Name - mongoddatadrive(replica set name)
- Mongo Data Blob Name - mongoddblob(instance id).vhd

**FAQ/Troubleshooting**

- Can I run mongo.exe to connect?
  - Yes if you set up remote desktop. Then you can connect to the any of the worker role instances and run e:\approot\MongoDBBinaries\bin\mongo.exe.
- Role instances do not start on deploy to Azure
  - Check if the storage URLs have been specified correctly.
- Occasional socket exception using the .Net driver on Azure
  - This is usually due to the fact that the Azure load balancer has terminated an inactive connection. This can be overcome by setting the max idle connection time on the driver.
• My mongodb instances are running fine on the worker roles, the included manager app shows the instances are working fine but my client app cannot connect
  • Ensure that the Instance Maintainer exe is deployed as part of the client role. You also need to change the Service Definition for the client role to have the InstanceMaintainer started on instance start. Refer to images below:
  Instance Maintainer deployed as part of role

```
MongoDefaults.MaxConnectionIdleTime = TimeSpan.FromMinutes(1);
```

```
Instance Maintainer deployed as part of role

Instance Maintainer start defined in service definition

    <WebRole name="MongoDB.WindowsAzure.Manager" winSize="Small">
    <Startup>
        <Task commandLine="InstanceMaintainer.cmd" executionContext="elevated" taskType="background"/>
    </Startup>

MongoDB on Azure - Building an Application

• Overview
• Connecting to MongoDB
• Configuration
  • Specifying replica set name
  • Setting up host aliases
  • Ensure the instance maintainer is started

This page outlines the steps necessary to setup your application to connect to the MongoDB cluster running on Azure worker roles. It is not a tutorial on building an application.

Overview

When connecting to a MongoDB replica set, the client application (driver) needs to be able to connect individually to each of the members of the replica set to route reads and writes appropriately. Also with the MongoDB worker role being deployed with Internal Endpoints (only accessible from within the same service), the client application needs to be deployed as part of the same cloud service as the MongoDB application. MongoDB.WindowsAzure.Sample.MvcMovie is an example client application that follows the steps described below. This sample application along with its deployment cloud project can be found in the MongoDB on Azure Github repos.

Connecting to MongoDB

Use the ConnectionUtilities class included as part of the MongoDB.WindowsAzure.Common project. To connect to the MongoDB replica set deployed as part of your cloud service, you need to:

Use the MongoDB.WindowsAzure.Common project
using MongoDB.WindowsAzure.Common;

Use the following code snippet to obtain a replica set connection to the database

```csharp
MongoServerSettings serverSettings = ConnectionUtilities.GetConnectionSettings();
MongoServer server = MongoServer.Create(settings);
MongoDatabase database = server["mydb"];  
```

To create a connection that allows reading from secondaries use:

```
MongoServerSettings serverSettings = ConnectionUtilities.GetConnectionSettings();
settings.SlaveOk = true;
MongoServer server = MongoServer.Create(settings);
MongoDatabase database = server["mydb"];  
```

More information on the `MongoDB .Net Driver ConnectionSettings` object can be found in the API docs.

**Configuration**

To account for possible changes in the IPs of the instances running MongoDB, the worker role uses the hosts file to alias each of the instances. Hence the client application instance needs the same instances. Additionally the client application needs to also have the name of the replica set.

**Specifying replica set name**

Ensure your client application deployment project has a setting called `ReplicaSetName` that is set to the same value as the `ReplicaSetName` setting of the MongoDB.WindowsAzure.MongoDB role. This can be verified by ensuring your `ServiceDefinition.csdef` file has the following setting as part of your client application role:

```
<ConfigurationSettings>
  <Setting name="ReplicaSetName" />  
</ConfigurationSettings>
```

Also your `ServiceConfiguration.*.cscfg` files have the value set:

```
<Role name="MongoDB.WindowsAzure.Sample.MvcMovie">
  <Instances count="1" />  
  <ConfigurationSettings>
    <Setting name="ReplicaSetName" value="rs" />  
  </ConfigurationSettings>
</Role>
```

**Setting up host aliases**

The included MongoDB.WindowsAzure.InstanceMaintainer utility takes care of correctly creating the hosts file. Include this as part of your client application project and ensure it is always deployed to the Azure role instance. e.g. in the sample MongoDB.WindowsAzure.Sample.MvcMovie application the following is specified in the csproj:

```
<None Include="..\..\..\MongoDB.WindowsAzure.InstanceMaintainer\$(InstanceMaintainerPath)\MongoDB.WindowsAzure.InstanceMaintainer.exe.config">
  <CopyToOutputDirectory>Always</CopyToOutputDirectory>
  <Link>MongoDB.WindowsAzure.InstanceMaintainer.exe.config</Link>
</None>
```
Ensure the instance maintainer is started

The InstanceMaintainer utility needs to be always running on your client application role to ensure it maintains the hosts file. To enable that it needs to be started as part of your role startup. This is done through the Startup setting on your csdef file. e.g. In the included MvcMovie sample app, this is specified as:

```xml
<WebRole name="MongoDB.WindowsAzure.Sample.MvcMovie" vmsize="Small">
  <Startup>
    <Task commandLine="InstanceMaintainer.cmd" executionContext="elevated" taskType="background" />
  </Startup>
</WebRole>
```

MongoDB on Azure Worker Roles - Configuration

- **MongoDB.WindowsAzure.MongoDBRole configuration**

The following are the configuration options available as part of the MongoDB Worker Role.

**MongoDB.WindowsAzure.MongoDBRole configuration**

- **Configuration**
  - **.Net Trust Level** - Ensure this is set to Full Trust
  - **Instance count** - Set to the number of replica set members you require. Default is 3.
  - Setting this to 1 would run a replica set with 1 instance (equivalent to stand alone)
  - **VM Size** - Choose size of Medium or higher. **Note** The I/O characteristics of small or extra small instance make these configurations unsuitable for MongoDB.

- **Settings**
  - **MongoDBDataDir** - Storage for mongo data files --dbpath. Configure for development or deployment. Data files are in a subdirectory called data. Default is local DevStorage.
  - **MongoDBDataDirSizeMB** - Size of blob (in MegaBytes) allocated for mongodb data directory. Default is 1GB for the emulator and 100GB for deployed.
  - **ReplicaSetName** - Name of the mongodb replica set. Default is rs. This also serves as the blob container name
  - **MongoDBLogVerbosity** - Verbosity to start mongod with. Default is null.
  - **RecycleOnExit** - This dictates whether the worker role is recycled when MongoDB exits. Default is false. Hence if mongod process exits the worker role instance is still up.

The following image shows the settings required in a local context.
- **Endpoints**
  - **MongodPort** - Port on which mongod listens. Default is 27017. If running locally on the Azure emulator this is port for the first instance that is started.

- **Local Storage**
  - **MongoDBLocalDataDir** - This specifies the size of the local storage used as a cache for the Windows Azure Drive used as the mongod data directory. Larger sizes provide better read performance.
  - **MongodLogDir** - Size of storage allocated for mongod.log. Make this large enough depending on verbosity chosen and instance size.
    Use the default settings for local storage as specified below when running on the Azure emulator. When deploying to Azure, change local storage size based on instance size chosen.
  - **BackupDriveCache** - Size of local storage used as cache during the backup process.
MongoDB on Azure Worker Roles - Deployment

The screenshots in this article refer to the older (pre-June 2012) Windows Azure portal, but the functionality is the same.

- In a development environment
- In the Azure environment
  - Azure setup (first time only per deployment)
    - Affinity Group
    - Storage account
    - Service
  - Deployment configuration for MongoDB.WindowsAzure.Sample.MvcMovie web role
    - Settings
  - Deployment configuration for MongoDB.WindowsAzure.Manager web role
    - Settings
  - Deployment configuration for MongoDB.WindowsAzure.MongoDBRole worker role
    - Configuration
    - Settings
    - Local Storage
    - Package and Publish

*In a development environment*

The solution can be built and run in a development environment using the Azure emulators as is using Visual Studio 2010 (if adequate disk space is available). Since this solution uses Cloud Drive you cannot run from a development environment against Azure cloud storage. Instead, when you run in your development environment it uses development storage:

- The mongod log file is at
  C:\Users\<user>\AppData\Local\dftmp\Resources\<deploymentid>\directory\MongodLogDir
  **Note** - On a development environment the port mongod listens on would be configured port (27017 by default) + instance id.
- The mongod data files are at
  C:\Users\<user>\AppData\Local\dftmp\wadd\devstoreaccount1\mongoddata\drive\<replica set name>\mongoddblob\<instance id>.vhd\data.
  **Note** - Additionally when the app is running you should be able to access the drives on mounting as you would access any mounted drive.

*In the Azure environment*

Login to the Azure management portal using your azure credentials

*Azure setup (first time only per deployment)*

*Affinity Group*

Create an affinity group for your deployment. Choose your required location for the group.
**Storage account**

Create the required number of storage account(s) to store the blobs. For region/affinity choose the affinity group you created earlier. **Note** The access key for the storage account created is the one you need to specify in your cloud configuration.

![Create a New Storage Account window](image)

**Service**

Create a new hosted service to host your Mongo package. For region/affinity group use the same affinity group as your storage account. **Note** for cloud drives the compute and storage instances should be in the same azure domain. Choose do not deploy.
Deployment configuration for MongoDB.WindowsAzure.Sample.MvcMovie web role

If deploying the sample application you can use the default settings as is. You would only need to set the storage settings for diagnostics.

**Settings**

In the Settings tab:

- **ReplicaSetName** - This should be the same as the replica set name specified in the MongoDB.WindowsAzure.MongoDBRole
Deployment configuration for MongoDB.WindowsAzure.Manager web role

To deploy the manager application you can use the default settings as is. You would only need to set the storage settings for diagnostics and mongod data directory.

**Settings**

In the Settings tab

- **ReplicaSetName** - This should be the same as the replica set name specified in the MongoDB.WindowsAzure.MongoDBRole
- **MongoDBDataDir** - Ensure that connection mode is http

![Configuration settings](image)

Deployment configuration for MongoDB.WindowsAzure.MongoDBRole worker role

**Configuration**

- Ensure VM size for ReplicaSetRole is at least Medium. Larger instance sizes provide more RAM and also greater bandwidth. More information on instance sizes can be found [here](#).
- Set the Instance Count equivalent to the required number of replica set members. Default is 3.

**Settings**

Edit connection settings to use actual storage account credentials (created earlier). It is recommended to use different storage accounts for data and diagnostics. This would allow you to give access to external monitors for diagnostics information without giving access to your data.

- **MongoDBDataDir** - Ensure that connection mode is http
- **ReplicaSetName** - This is the name of the replica set in the replica set configuration. This is also the suffix to the blob container created in your storage account. **Note** - This needs to be the same as the replica set name in the client applications.
- **MongoDBDataDirSize** - Maximum size of your cloud drive where mongod data files are stored. Currently the maximum size can be 1TB.
- **MongoDBLogVerbosity** - Verbosity for mongod logging. Default is null
- **RecycleOnExit** - This dictates whether the worker role is recycled when MongoDB exits. Default is false.
- **Microsoft.WindowsAzure.Plugins.Diagnostics.ConnectionString** - Ensure that the connection mode is https
Note - If deploying multiple Azure instances make sure you use different storage accounts for each of the deployments or different replica set names if using the same storage account.

Local Storage

Configure the amount of local storage required depending on the VM size chosen. Ensure Clean on recycle role is unchecked. The following are recommendations of Local Storage **Note** All sizes are in MB.

<table>
<thead>
<tr>
<th>VM Size</th>
<th>MongoDBLocalDataDir</th>
<th>MongodLogDir</th>
</tr>
</thead>
<tbody>
<tr>
<td>Medium</td>
<td>256000 (250 GB)</td>
<td>51200 (50GB)</td>
</tr>
<tr>
<td>Large</td>
<td>788000 (750 GB)</td>
<td>51200 (50GB)</td>
</tr>
<tr>
<td>Extra Large</td>
<td>1024000 (1000GB)</td>
<td>51200 (50GB)</td>
</tr>
</tbody>
</table>

Package and Publish

Create the Azure package by right clicking on the cloud project and choosing Package. Choose the Service Configuration as Cloud and Build Configuration as Release.

Deploy the created package from the Azure management portal. More details on deploying can be found at http://msdn.microsoft.com/en-us/magazine/ee336122.aspx

When deploying to the Azure cloud make sure to check deployment warnings/errors to see for any breaking issues. Some common errors are

- Remote desktop is enabled but the remote desktop certificate has not been uploaded to the portal
- https is not chosen for diagnostics connection string
- If deploying the sample MvcMovie application, you can safely ignore the warning that indicates you are only running 1 instance of it.

Rackspace Cloud

- Deployment Planning
  - Instance sizes
  - Topology
  - Security
  - Monitoring
- Deploying a Single Node
  - Creating an Instance
  - Securing Your Instance
  - Installing MongoDB
  - Configuring MongoDB
- Replica Sets
- Backups
  - Cloud Servers Images
  - Built-in Tools

This guide is intended to provide instructions on getting started with MongoDB using Rackspace Cloud Servers.

First we’ll step through deployment planning (instance sizes, topology, security) and then we’ll set up a single MongoDB node. We’ll use the same steps to create a multi-node replica set and cover the steps needed to backup your database.

Deployment Planning

Instance sizes

Rackspace Cloud offers instances with RAM ranging from 256 MB up to 64 GB. When considering instances for initial development purposes, those with 256 or 512 MB are an appropriate starting point. As development progresses towards production-level deployments we recommend moving to higher memory instances. The top-end Cloud instances are appropriate for pre-production and some production deployments. If you need to grow your deployment beyond the Cloud instances, Rackspace also offers managed dedicated servers that can be scaled to increase database performance and throughput.

When planning your deployment, it’s important to account for your resource needs for today and into the future. If you plan on growing your production systems into Rackspace’s dedicated services then it may be useful to consider using RackConnect. This is a service that bridges Rackspace’s public cloud infrastructure with their private dedicated servers. It makes migrating from Cloud to dedicated much easier and is also useful when creating a hybrid deployment solution combining resources from both. For more information refer to Rackspace’s RackConnect site.

Topology

The following are example deployment scenarios for MongoDB built on Rackspace servers.

The single node example is the simplest; a single MongoDB instance can be deployed in Rackspace Cloud or Managed hosting. This deployment is useful for development and early app testing.
For production-level deployments, we'll move to a three node Replica Set running in Rackspace Cloud.

Depending on the size of your database deployment or if your app requires greater levels of database performance, another option is a hybrid deployment. In this case, a Replica Set which spans Rackspace Cloud and Managed hosting can be deployed. Cloud and Managed hosting are "connected" via RackConnect, providing a faster interconnect between the two hosting services.

**Security**

When deploying onto Rackspace Cloud, you'll need to secure access to your instances so that MongoDB is only available to known safe systems. To secure your instances we'll use the `iptables` command-line tool to control access to the system with a firewall. Once we've completed securing our instance, it will be using the following firewall configuration:

- port 22 (SSH) will accept any incoming TCP connections
- All other ports will reject incoming TCP connections

Later on when we deploy multiple instances we'll open up port 27017 (for mongod) to other specific IP addresses in order to facilitate a working replica set. The ports required for sharding (27018 and 27019) aren't required immediately since we'll be setting up a single node and replica set however just remember to open them up later if necessary.

**Monitoring**

Monitoring is a critical component of all database servers. MongoDB includes several tools to help gather statistics about data sizes, index sizes
and analyze queries. In addition, there are several third-party tools that exist to help integrate MongoDB information into other monitoring solutions. 10gen also offers MongoDB Monitoring Service, a free hosted SaaS monitoring solution that provides custom dashboards and reporting for your MongoDB instances. For more information, refer to Monitoring and Diagnostics.

**Deploying a Single Node**

**Creating an Instance**

Log in to the Rackspace Cloud control panel and navigate to Hosting > Cloud Servers > Add Server. In this example we used Ubuntu 11.10 (Oneiric Ocelot) as the OS image for our instance. Once selected, enter a server name, select a server size and continue. Be sure to record your root password or you'll have to reset it later. Once the instance is available, connect to it via SSH to secure it. By default, you'll be connecting to the server as root. If you'd like to create additional users/groups to use with your instance, consult the documentation for the chosen OS. For our configuration, we used the admin group and added an additional user, per the Ubuntu 11.10 server guide.

First we added a new user (admin) to the admin group:

```
root# adduser admin --ingroup admin
```

After stepping through the prompts to set a password (and other account information), the admin user will be created and added to the admin group.

At this point, log out of the server as root and login as admin.

**Securing Your Instance**

As discussed above in Security, we'll use a simple firewall setup to secure access to the instances running MongoDB. The built-in `ufw` command provides a simple mechanism to configure the system firewall. First off, enable the firewall and add a rule to allow SSH access:

```
$ sudo ufw enable
$ sudo ufw allow 22
```

Now the only port that will allow connections is port 22. attempts to connect on any other port will be dropped. With this firewall setup, the instance is secure and we can proceed with configuring MongoDB. For more information, refer to the Rackspace Introduction to IPTables and the Ubuntu firewall guide.

**Installing MongoDB**

Using the instructions from the MongoDB documentation on Ubuntu and Debian packages we added an additional `apt-get` source and installed MongoDB.

First add the 10gen GPG key to `apt-get` to create a "trusted" source:

```
$ sudo apt-key adv --keyserver keyserver.ubuntu.com --recv 7F0CEB10
```

Next, add the following line to `/etc/apt/sources.list`:

```
$ sudo nano /etc/apt/sources.list
...
deb http://downloads-distro.mongodb.org/repo/ubuntu-upstart dist 10gen
...
```

Now update `apt-get` to pickup the new packages:

```
$ sudo apt-get update
```

Finally, install MongoDB:
At this point MongoDB will be installed and started, which we can confirm via the service utility:

```
$ sudo service mongodb status
mongodb start/running, process 2308
```

You can also check the status by using `tail` to examine the MongoDB log:

```
$ sudo tail -f /var/log/mongodb/mongodb.log
```

**Configuring MongoDB**

By default, MongoDB is set to use `/var/lib/mongodb` as the data path. If you’d like to amend that, or update the log path, shutdown the MongoDB instance and update `/etc/mongodb.conf` with any changes.

If you change the MongoDB `dbpath` or `logpath`, be sure to set the proper ownership, etc. For example, to change MongoDB to use `/data` as the data path, use the following steps.

First, shutdown the MongoDB service:

```
$ sudo service mongodb stop
```

Next, update the MongoDB configuration file:

```
$ sudo nano /etc/mongodb.conf
... 
  dbpath=/data
... 
```

Now create the `/data` directory and update it's ownership:

```
$ sudo mkdir /data
$ sudo chown mongodb:mongodb /data
```

Restart MongoDB with

```
$ sudo service mongodb start
```

**Replica Sets**

MongoDB Replica Sets are a form of asynchronous data replication between primary/secondary instances of MongoDB, adding automatic failover and automatic recovery of secondary nodes. In addition, Replica Sets can also provide the ability to distribute the read workload of your data.

To create a Replica Set, first create three instances of MongoDB using the instructions above in [Creating an Instance]. Next follow the instructions to [install] and [configure] MongoDB on each instance. Just before starting MongoDB, edit the `/etc/mongodb.conf` configuration file adding the `replSet` parameter:
Before proceeding, note that our current security setup has blocked access to all incoming ports (other than port 22 for SSH) therefore the MongoDB instances won’t be accessible. We’ll need to add rule to each instance that allows access to port 27017 (the standard mongod port) from the other instances in our replica set.

Collect the IP addresses of the instances in your Replica Set and execute the following ufw commands on each instance:

```
$ sudo ufw allow proto tcp from [IP Address 1] to any port 27017
$ sudo ufw allow proto tcp from [IP Address 2] to any port 27017
$ sudo ufw allow proto tcp from [IP Address 3] to any port 27017
```

Then start MongoDB with

```
$ sudo service mongodb start
```

Once MongoDB has started and is running on each instance we’ll connect to the desired primary node, initialize the Replica Set and add the secondary nodes. First connect to the desired primary node and launch the mongo shell:

```
$ mongo
MongoDB shell version: 2.0.4
connecting to: test
>
```

Now initialize the Replica Set:

```
> rs.initiate()
{   "info2" : "no configuration explicitly specified -- making one",   "me" : "67.207.133.237:27017",   "info" : "Config now saved locally. Should come online in about a minute.",   "ok" : 1 }
```

Next add the other nodes to the Replica Set. If you’re executing this on the first configured instance, add the other 2 instances here:

```
> rs.add("[IP Address 2]");
{ "ok" : 1 }
PRIMARY> rs.add("[IP Address 3]");
{ "ok" : 1 }
```

Finally, you can check the status of the Replica Set from the Mongo shell with the following:

```
PRIMARY> rs.status()
...
```

In the output of the `rs.status()` command, you should see three entries, one for each instance. Each one should provide information about it's current status within the Replica Set. For more information, refer to the Replica Sets documentation.
Backups

To facilitate backups there are two main options: Cloud Servers images or MongoDB built-in backup tools.

**Cloud Servers Images**

Cloud Servers images are snapshots of an entire instance which are saved in Rackspace Cloud Files. Images can be created from any running instance and the process can be completed via the Rackspace Cloud control panel. When creating backups from instances in a Replica Set, be sure to image a SECONDARY instance to avoid any interruptions for your applications or data. To image a SECONDARY, first lock it against database writes from within the Replica Set, create the image and then unlock it to rejoin the Replica Set.

To lock the SECONDARY database, connect with the Mongo shell and use the following command:

```javascript
SECONDARY> db.fsyncLock()
{
    "info": "now locked against writes, use db.fsyncUnlock() to unlock",
    "seealso": "http://www.mongodb.org/display/DOCS/fsync+Command",
    "ok": 1
}
```

While the database is locked it will not accept any incoming writes from the PRIMARY instance. Once locked, go to the Rackspace Cloud control panel and create a "New On-Demand Image". Once the image has been created and is complete, go back to the Mongo shell and issue the "unlock" command:

```javascript
SECONDARY> db.fsyncUnlock()
{
    "ok": 1,
    "info": "unlock completed"
}
```

Once unlocked, any data that was written to the PRIMARY while the SECONDARY was locked will asynchronously replicate to the newly unlocked SECONDARY.

**Built-in Tools**

MongoDB ships with several built-in command line tools to help with database administration. One of those tools `mongodump` can be used to create file-based backups of the running database. Mongodump can be used on a live database instance however for the sake of data consistency, it is wise to use the `--oplog` option when calling `mongodump`. This allows for point-in-time backups that catch any data that was written while `mongodump` was working. For more information about live data backups, refer to the `mongodump documentation`.

**RedHat OpenShift**

- Getting Started
- Documentation
- Sample MongoDB Apps
- Additional Information

OpenShift is a Platform as a Service (PaaS) offering from RedHat, which provides support for rapid deployment and automatic scalability support for web applications developed with Java EE, Node.js, Python, PHP, Perl and Ruby, and several databases including MongoDB.

**Getting Started**

To get started with OpenShift and MongoDB, check out the OpenShift Quickstart guide. The guide reviews the steps necessary to create, deploy and manage your MongoDB-backed apps. The guide also covers things like application snapshots and database backups.

**Additional Information**
OpenShift Quickstart

- Cloning the App
- Deploying onto Express
- Testing the Deployment
- Advanced Functionality
  - App Administration
- Additional Information

OpenShift is a Platform as a Service (PaaS) offering from RedHat, which provides support for rapid deployment and automatic scalability support for web applications developed with Java EE, Node.js, Python, PHP, Perl and Ruby. OpenShift Express is a free shared-cloud solution for deploying your applications. With Express, you simply push your app using the command line tools to OpenShift and the platform takes care of the hosting infrastructure.

In this guide, we'll take a simple Java web application and deploy it onto OpenShift Express. We'll walk through the steps required to setup and administer MongoDB as well as backing up your data.

Cloning the App

We'll be deploying an existing Java web application onto OpenShift. The app is a simple REST-style checkin mechanism with a single endpoint. The app supports POST-ing new checkins (by supplying a comment and location) and GET-ing checkins near a given location (by supplying a pair of coordinates). The app was built using Java SE 6 and Maven. Make sure to have those components installed, along with Git for your platform, before continuing.

First, start by cloning the repository for the web application:

```
$ git clone https://github.com/crcsmnky/openshift-checkins.git
$ cd openshift-checkins
```

Next, make sure you can build the app as-is using Maven:

```
$ mvn package
```

If that completes successfully, you're ready to move on. To prepare our app for deployment, we'll need to setup our OpenShift Express account.

Deploying onto Express

To deploy apps onto Express you'll need to create an OpenShift account from the OpenShift sign up page and install the OpenShift command line tools.

First, follow the steps from the OpenShift Express getting started guide in the "Install the client tools" section for your platform. Once the tools have been installed we'll create a domain name, app name and then push the sample app to OpenShift Express (the URL for the app will be something like **http://appname-domainname.rhcloud.com**).

First, create the domain name:

```
$ rhc domain create -n your-domain -l your-openshift-login
```

This command will prompt you for your account password then for an SSH passphrase (it generates a public/private keypair to use for connecting to the OpenShift service). Next, create an entry for the app that we'll be deploying. Here you'll need to supply the app name (example, expresscheckin) and jbossas-7.0 as the app type:
$ rhc app create -a expresscheckin -t jbossas-7
Password:
Creating application: expresscheckin
Now your new domain name is being propagated worldwide (this might take a minute)...
Warning: Permanently added 'expresscheckin-your-domain.rhcloud.com,50.16.164.248' (RSA) to the list of known hosts.
Confirming application 'expresscheckin' is available: Success!
expresscheckin published: http://expresscheckin-your-domain.rhcloud.com/
git url: ssh://429827960cbf4518b1785ed928db9be7@expresscheckin-your-domain.rhcloud.com/~git/expresscheckin.git/
Successfully created application: expresscheckin

After the app is created the command will also clone the app’s repository locally. Before continuing, we need to set up MongoDB on OpenShift and also update our app’s MongoDB connection information:

$ rhc app cartridge add -a expresscheckin -c mongodb-2.0
RESULT:  
MongoDB 2.0 database added. Please make note of these credentials:

   Root User: admin
   Root Password: 1wbLGYAmPgDM
   Database Name: expresscheckin
   Connection URL: mongodb://127.6.85.129:27017/

You can manage your new MongoDB by also embedding rockmongo-1.1

Now that we’ve added support for MongoDB to our app (on OpenShift) we’ll need to take the credentials returned and update our openshift-checkins app configuration. Go back to the openshift-checkins directory and edit CheckinServlet.java and add/update the following lines in the `init` function using the MongoDB details provided by OpenShift (don’t forget to uncomment the `if` statement with the authentication statement):

```java
$ cd openshift-checkins
$ nano src/main/java/CheckinServlet.java
...
conn = new Mongo("127.6.85.129", 27017);
db = conn.getDB("expresscheckin");
if (db.authenticate("admin", "1wbLGYAmPgDM".toCharArray())) {
    throw new MongoException("unable to authenticate");
} 
...
```

Then build the openshift-checkins WAR file:

$ mvn package

Now, return to the cloned repository, remove the sample code generated from the expresscheckin app repo that was cloned to our system and copy the checkins.war file into the deployments as ROOT.war:

$ cd ../expresscheckin
$ rm -rf pom.xml src
$ cp ../openshift-checkins/target/checkins.war deployments/ROOT.war

As part of the deployment process, we also need to flag our WAR file to be deployed (expanded and copied to the right places):
$ touch deployments/ROOT.war.dodeploy

Now we can add it to the repository, commit and push:

$ git add -A
$ git commit -m "initial deployment of expresscheckin app onto OpenShift Express"
$ git push origin

After pushing the app, it will take a few minutes for the app to become available at http://expresscheckin-your-domain.rhcloud.com/. That's it, you've deployed a simple Java app that uses MongoDB to OpenShift Express. Refer to Testing the Deployment below for some notes on testing the app's functionality.

**Testing the Deployment**

Once you've deployed your app onto OpenShift Express, the URL for the app will be something of the form http://expresscheckin-your-domain.rhcloud.com. We'll now use that URL to conduct some tests on our deployed app.

Since the app is a simple RESTish mechanism we can use curl to test it out. Let's start by posting a new comment and location to the URL (ex. http://appurl.rhcloud.com/checkin):

$ curl -X POST -d "comment=hello&x=1&y=1" http://appurl.rhcloud.com/checkin

Now let's see if we can find the comment we just posted at that location (x = 1, y = 1):

$ curl "http://appurl.rhcloud.com/checkin?x=1&y=1"

{ "_id" : { "$oid" : "4f0e068c3004bfd40822840b" } , "comment" : "hello" , "location" : [ 1.0 , 1.0] }

If these worked, then it looks like we've got a functional app deployed onto OpenShift.

**Advanced Functionality**

Once you've deployed your app, you'll probably need to connect to your server at some point so you can do things like reviewing app logs or query data in MongoDB. The following steps will cover how you can do that (and if available, set up some advanced functionality).

**App Administration**

Using the command line tools, we can connect to the server our app is deployed on. Run the following command to get information about the current running apps:
The **UUID** above shows the user ID we can use to SSH into our server::

```bash
$ ssh 429827960cbf4518b1785ed928db9be7@expresscheckin-your-domain.rhcloud.com
```

Welcome to OpenShift shell

**!!! IMPORTANT !!! IMPORTANT !!! IMPORTANT !!!**

Shell access is quite powerful and it is possible for you to accidentally damage your application. Proceed with care!
If worse comes to worse, destroy your application with rhc-ctl-app and recreate it
**!!! IMPORTANT !!! IMPORTANT !!! IMPORTANT !!!**

type "help" for more info.

Now at the prompt type `help` to see the available commands (in addition to normal shell commands)::

```
[openshift]$: help
Help menu: The following commands are available to help control your openshift application and environment.

ctl_app control your application (start, stop, restart, etc)
ctl_all control application and deps like mysql in one command
tail_all tail all log files
export list available environment variables
rm remove files / directories
ls list files / directories
ps list running applications
kill kill running applications
mongo interactive MongoDB shell
```

To connect to MongoDB, we'll need to use the credentials provided to us from OpenShift above when we set it up initially. Once you have those in hand, here's how you should connect to the database::
From here you can query your data as needed for your application. Finally, to backup your app's data, follow the instructions found on the MongoDB Backup docs. Specifically you'll need to use the `mongodump` command to do a live backup of your data.

Backing up your app is a simple single step where we create a "snapshot" of the entirety of the application including data, which we can do locally on our development machine:

```
$ rhc app snapshot save -a expresscheckin
Password:
Pulling down a snapshot to expresscheckin.tar.gz
Running extra dump: mongodb_dump.sh
MongoDB already running
Stopping application...
Done
Creating and sending tar.gz
Running extra cleanup: mongodb_cleanup.sh
Starting application...
Done
```

Additional Information

For additional information, refer to the following:

- OpenShift Express User Guide or
- OpenShift Flex User Guide

**VMware CloudFoundry**

MongoDB is a supported service on VMware's Cloud Foundry.

Cloud Foundry is a platform-as-a-service solution. At this time, CloudFoundry.com (the public instance of Cloud Foundry operated by VMware) supports applications written in Spring Java, Rails and Sinatra for Ruby, Node.js, Scala and other JVM languages/frameworks including Groovy and Grails.*

**Starting a MongoDB service**

```
vmc create-service mongodb --name MyMongoDB
```

Once you create a MongoDB service, you can bind and use it inside of Cloud Foundry applications.

**Java**

JS Benchmarking Harness

This `benchRun` command is designed as a QA baseline perf measurement tool, not designed to be a "benchmark".

CODE:

```javascript
db.foo.drop();
db.foo.insert( { _id : 1 } )

ops = [{op: "findOne", ns: "test.foo", query: { _id: 1 }},

for ( var x = 1; x <= 128; x *= 2 ) {
  res = benchRun( {
    parallel : x ,
    seconds : 5 ,
    ops : ops
  } );
  print( "threads: " + x + "\ queries/sec: " + res.query );
}
```

Dynamic values
// benchmark updates using the $inc operator
res = benchRun( {
    ops : [ {
        ns : "test.foo",
        op : "update",
        query : { _id : { "$RAND_INT" : [ 0 , 100 ] } },
        update : { $inc : { x : 1 } }
    } ],
    parallel : 2,
    seconds : 1,
    totals : true
} );
print( "threads: 2	 update/sec: " + res.update );

// benchmark inserts with random strings
res = benchRun( {
    ops : [ {
        ns : "test.foo",
        op : "insert",
        doc : { y : [ 10 ] }
    } ],
    parallel : 2,
    seconds : 1,
    totals : true
} );
print( "threads: 2	 insert/sec: " + res.insert );

Options

- **host** - the hostname of the machine mongod is running on (defaults to localhost)
- **username** - the username to use when authenticating to mongod (only use if running with auth)
- **password** - the password to use when authenticating to mongod (only use if running with auth)
- **db** - the database to authenticate to (only necessary if running with auth)
- **ops** - a list of objects describing the operations to run (documented below)
- **parallel** - the number of threads to run (defaults to single thread)
- **seconds** - the amount of time to run the tests for (defaults to one second)

Operation Options

- **ns** - the namespace of the collection you are running the operation on, should be of the form "db.collection"
- **op** - the type of operation can be "findOne", "insert", "update", "remove", "createIndex", "dropIndex" or "command"
- **query** - the query object to use when querying or updating documents
- **update** - the update object (same as 2nd argument of update() function)
- **doc** - the document to insert into the database (only for insert and remove)
- **safe** - boolean specifying whether to use safe writes (only for update and insert)

Dynamic operators

- `{ "$RAND_INT" : [ min , max , <multiplier> ] }`
- `[ 0 , 10 , 4 ]` would produce random numbers between 0 and 10 and then multiply by 4
- `{ "$RAND_STRING" : [ length ] }`
- `[ 3 ]` would produce a string of 3 random characters

Dynamic operators generate random strings, random ints, etc but don’t work in second level objects, just main level

- This is fine
  ```
  var complexDoc3 = { info: "$RAND_STRING": [30] }
  ```

- This is only going to insert a value called "$RAND_STRING" with an array as a key

**MongoDB kernel code development rules**

- C++ Style Guide
- JS Style Guide
- Git Committing and Pushing
- User Facing Conventions
  - Use camelCase for about everything
  - Include units in fields

**C++ Style Guide**

Coding conventions for the MongoDB C++ code...

- Kernel class rules
- Kernel code style
- Kernel concurrency rules
- Kernel exception architecture
- Kernel logging
- Kernel string manipulation
- Memory management
- Writing tests

For anything not mentioned here, default to google c++ style guide

**JS Style Guide**

10gen follows the google javascript style guide

**Git Committing and Pushing**

- commit messages should have the case in the message SERVER-XXX
- commit messages should be descriptive enough that a glance can tell the basics
- commits should only include 1 thought.
- do NOT push until running the test suite

**User Facing Conventions**

> These are very important as we can't change them easily – Much more than code conventions!

Anything users see – command line options, command names, command output, we need to think hard and carefully about the name to be used, and the exact format and consistency of the items output. For example, serverStatus output is a bit of a mishmash of lowercase and camelCase. Let's fix that over time, starting with new things.

Anything user facing must be ran by several team members first.

- Do NOT add a new $operator without signoff by the entire team.
- Do NOT add a new command without signoff by the entire team.

Use camelCase for about everything

- --commandLineOptions
- { commandNames : 1, commandOption : "abc" }
- Names of fields in objects we generate - such as command responses, profiler fields.

Include units in fields
In things like serverStatus, include the units in the stat name if there is any chance of ambiguity. For example:

- writtenMB
- timeMs

We should have standards for these – i.e. megabytes should always be "MB" and not "Mb" and "Megabytes" in different places. So the standards are:

- for bytes: use "MB" and show in megabytes unless you know it will be tiny. Note you can use a float so 0.1MB is fine to show.
- for time: use millis ("Ms") for time by default. you can also use Secs and a float for times you know will be very long.
- for microseconds, use "Micros" as the suffix, e.g., timeMicros.

Kernel class rules

Design guidelines

- **Never use multiple inheritance.** If you need the service of several classes, use delegation. The only possible but highly unlikely exception to this is if your class inherits from other pure abstract classes.
- Have a comment before a class that explains its purpose. Perhaps the class name is so clear that this is obvious. Then some commentary on what you are up to.
- Only add **members and methods to a class if they make sense** w.r.t the bullet above. If you find yourself unsure to where to hook a piece of logic, rethink the class and surrounding classes purposes.
- Class **names and methods names are to be descriptive** of what they do. Avoid generic overloaded names (e.g., write, add, ...) to make grep easier (and maybe reading too).
- Don't put implementation details in the header unless the user of the class needs to know them. Sometimes single line inline implementations are good "documentation". If something needs to be inline for performance, put it at the bottom of the file using the inline keyword instead of in the middle of the class definition (if the implementation is more than a line or two long).
- Assume all methods can throw a DBException. If a class should never throw (e.g can be called in a destructor), that should be clear.
- **Write a unit test for each class you create.** If you can't easily write a unit test for the class, that is a strong hint it has way too many external dependencies.
- **Do not create early hierarchies.** An early hierarchy is a one where there is only one type of derived class. If you need to separate functionality, use delegation instead. In that case, make sure to test separately.
- Avoid friend.
- Default to making classes **non-assignable and non-copyable.** (Use boost::noncopyable.)

Layout guidelines

- For classes where layout matters (anything with #pragma pack), put data members together at the top of the class. You must also have a BOOST_STATIC_ASSERT(sizeof(ClassName) == EXPECTED_SIZE) either directly under the class or in the associated .cpp file

Kernel code style

- basics
- case
- comments
- inlines
- strings
- brackets
- class members
- functions
- templates
- namespaces
- start of file
- assertions
- return early
- numeric constants
- explicit constructors
- #includes
  - For cpp files:
  - For h files:
- file names
- casting
RAII and bare vs. smart pointers

basics
- Use spaces, no literal tabs.
- 4 spaces per indentation.
- Limit lines to 100 columns.
- Use LF (Unix-style) line endings, not CR-LF (DOS)
  - git has a config option in Windows to convert line endings automatically (core.autocrlf)
- For anything that isn't explicitly covered here, default to the Google C++ Style Guide:
  http://google-styleguide.googlecode.com/svn/trunk/cppguide.xml

case

Use camelCase for most varNames

See important notes on case on the parent page for user facing names!

comments

We follow http://google-styleguide.googlecode.com/svn/trunk/cppguide.xml#Comments for placement of comments

As for style, we use javadoc's in classes and methods (public or private) and simple comments for variables and inside code

```cpp
/**
 * My class has X as a goal in life
 * Note: my class is fully synchronized
 */
class DoesX {
...
/**
 * This methods prints something and turns off the lights.
 * @param y the something to be printed
 */
void printAndGo(const std::string& y) const;
...
/**
 * Helper that finds the light switch
 */
Pos findSwitch() const;
/** @return the light switch state. */
State getSwitchState() const;
};

void DoX(bool y) {
  // if y is false, we do not need to do a certain action and explaining
  // why that is takes multiple lines.
  if (!y) {
    printf("y is true!\n");
  }
}
```

Don't forget – even if a class's purpose is obvious, you can put a comment on it as to why it exists!

inlines
- Put long inline functions in a `inl.h` file.
- If your inline function is a single line long, put it and its decl on the same line e.g.
int length() const { return _length; }

- If a function is not performance sensitive, and it isn't one (or 2) lines long, put it in the cpp file. Keep code out of headers.

**strings**

See

- util/mongoutils/str.h
- bson/stringdata.h

Use `str::startsWith()`, `str::endsWith()`, not `strstr()`.

Use `<< 'c'` not `<< "c"`.

Use `str[0] == '\0'` not `strlen(str) == 0`.

See Kernel string manipulation.

**brackets**

```cpp
if (0) {
} else if (0) {
} else {
}
do {
} while (0);
```

**class members**

```cpp
class Foo {
    int _bar;
};
```

**functions**

Declaration:

```cpp
void foo(int v, MyType myItem);
```

Avoid declarations of extern functions in source files! Instead, #include a proper .h file. Be sure to match the header filename to the source filename where the function definition appears.

Definition:

```cpp
void foo(int v, MyType myItem) {
}
```

Invocation:

```cpp
foo(1, MyType());
```

**templates**

```cpp
set<int> s;
```
namespaces

```cpp
namespace foo {
  int foo;
  namespace bar {
    int bar;
  }
}
```

start of file

license (AGPL or Apache, depending on C++ driverness)

assertions

See Kernel exception architecture.

return early

BAD

```cpp
int foo() {
  if (x) {
    ...
  }
}
```

GOOD

```cpp
int foo() {
  if (!x)
    return;
  ...
}
```

Keeps indentation levels down and makes more readable.

numeric constants

Large, round numeric constants should be written in multiplied form so that you never need to count digits.

```cpp
const int tenMillion = 10*1000*1000;
const int megabyte = 1024*1024;
```

explicit constructors

To avoid implicit type conversion, use the "explicit" keyword before constructors that take a single parameter.

#include

examples:

```cpp
#include "mongo/pch.h"
#include <boost/thread.h>
#include <vector>
```

#includes

- Use "double quotes" for 10gen code, <angle brackets> for 3rd party or library headers.

- Always use forward relative path from mongo/src/; do not use "./"
correct:
`#include "mongo/db/namespace_details.h"
incorrect:
`#include "../db/namespace_details.h"

For cpp files:
- Include `mongo/pch.h` first, blank line.
- Include your .h file next, if applicable, blank line.
- Include third party headers next, sorted, blank line.
- Include 10gen headers last, sorted.

example for classy.cpp:
```
#include "mongo/pch.h"

#include "mongo/db/classy.h"

#include <boost/thread.h>
#include <stdio.h>
#include <string>
#include "mongo/db/db.h"
#include "mongo/db/namespace_details.h"
#include "mongo/util/concurrency/qlock.h"
```

For h files:
- `#pragma once` at the top
- Forward declare, if possible, in lieu of including 10gen headers in headers. Only include things that are directly used in the header itself.
- Include third party headers first, sorted, blank line.
- Include 10gen headers last, sorted.
- Be extremely careful about including pch.h in a header.

file names
- Class definitions should go in a header file with the same name as the class. Insert _ in place of a capital letter. Do not use capital letters in filenames!
  example: ClassyClass's definition goes in "classy_class.h". ClassyClass's member function implementations go in "classy_class.cpp".
- Do not be afraid to make another file, even if it is really small. This is preferable to inserting your new class into a preexisting file.

casting
- Do not use C-style casts, ever.
- Use `static_cast<>` or `const_cast<>`.
- Be aware that `dynamic_cast<>`, unlike other casts, is done at run-time and calls a function.
  You should always check the return status of `dynamic_cast<>` for null.
- `reinterpret_cast<>` should be used sparingly and is typically done for converting structures to raw bytes for use with I/O drivers.

RAII and bare vs. smart pointers
- Aspire to embrace RAII
- When writing functions that take or return bare pointers, document the ownership semantics in the header comment. Is the caller responsible for managing returned pointer's memory? Does the callee take ownership of the pointed-to parameter, or does the caller retain ownership. Prefer caller-retains ownership of parameters and takes ownership of returned pointers, but use the appropriate policy for each situation.
- Generally, bare calls to delete and free() are red flags
  - except in destructors
- Use smart pointers such as boost::scoped_ptr and std::auto_ptr (know the difference between them!) to avoid memory leaks and ensure all new's and malloc's are paired with delete's and free's
- Use `ON_BLOCK_EXIT` or `ScopeGuard` to protect other resources that must be released
  - e.g. fopen/fclose pairs
  - Or, write an object to do this for you via constructor and destructor

Kernel concurrency rules
All concurrency classes must be placed under `utils/concurrency`. You will find several helper libraries there.

- Do not add mutexes without discussion with others. Concurrency and correctness is very hard in the large. Great care is required. For example the concurrency model in replica sets is hard to understand and error prone (at least it was initially and probably still is).

If you think there is a real need for an exception to the list below let's have the group weigh in and get a consensus on the exception:

- Do not use/add recursive locks.
- Do not use rwlocks.
- Always acquire locks in a consistent order. In fact, the MutexDebugger can assist with verification of this. MutexDebugger is on for _DEBUG builds and will alert if locks are taken in opposing orders during the run.

Kernel exception architecture

There are several different types of assertions used in the MongoDB code. In brief:

- `uassert` checks for per-operation user errors. Operation-fatal.
- `massert` checks per-operation invariants. Operation-fatal.
- `verify` is a synonym for massert, that doesn't require an error code.
- `fassert` checks fatal process invariants. Process-fatal.
- `wassert` warn (log) and continue.

Calling `assert` is not allowed. Use one of the above instead.

- `dassert` just calls `verify` but only in debug mode. Do not use!

When per-operation invariant checks fail, the current operation fails, but the process and connection persist. This means that `massert`, `uassert` and `verify` only terminate the current operation, not the whole process. Be careful not to corrupt process state by mistakenly using these assertions midway through mutating process state. Examples of this include uassert and massert inside of constructors and destructors. `fassert` failures will terminate the entire process; this is used for low-level checks where continuing might lead to corrupt data or loss of data on disk.

Both `massert` and `uassert` take error codes, so that all errors have codes associated with them. These error codes are assigned incrementally; the numbers have no meaning other than a way to associate a log message with a line of code. `scons` checks for duplicates, but if you want the next available code you can run:

```
python buildscripts/errorcodes.py
```

A failed operation-fatal assertion throws an `AssertionException` or a child of that. The inheritance hierarchy is something like:

- `std::exception`
  - `mongo::DBException`
    - `mongo::AssertionException`
      - `mongo::UserException`
      - `mongo::MsgAssertionException`

See `util/assert_util.h`.

Generally, code in the server should be prepared to catch a `DBException`. `UserAssertionException`'s are particularly common as errors and should be expected. We use `resource acquisition is initialization` heavily.

Gotchas to watch out for:

- generally, don't throw a `AssertionException` directly. Functions like `uasserted()` do work beyond just that. In particular, it makes sure that the `getLastError` structures are set up properly.
- think about where your asserts are in constructors, as the destructor wouldn't be called. (But at a minimum, use `wassert` a lot therein, we want to know if something is wrong.)
- don't throw in destructors of course.

Kernel logging

- Basic Rules
  - `cout/cerr` should never be used
    - Except early in process startup before the `log()` system is initialized
    - For such cases, it would be good to use `cerr`, but right now there is a mix of `cout` and `cerr`
  - Include `log_internal.h` to use the `LOG()` helper macro
    - Avoid including `log_internal.h` in any code that may pollute C++ driver headers.
    - Use `MONGO_LOG()` instead of `LOG()` for code included by C++ driver headers.

- Normal Logging
  - Debugging with levels of verbosity. See the `-v` command line option (default level is 0). If the global log level is less than x, no functions in the steam are executed.
- **LOG( int x ) << ...**
- **Informational**
  - log() << ...
- **Rate limited**
  - LOGSOME() << ...
- **Warnings**
  - recoverable
    - e.g. replica set node down
  - warning() << ...
- **Errors**
  - unexpected system state (disk full)
  - internal code errors
    - error() << ...
- **Debugging Helpers**
  - PRINT(x) = prints expression text and value (can also do PRINT(x.method()))
  - PRINTFL = prints file and line (good for tracing execution)
  - printStackTrace() = shows a stack trace. Alternative to using a debugger.
  - GEODEBUG, etc... = used for incredibly verbose logging for a section of code that has to be turned on at compile time

**Kernel string manipulation**

For string manipulation, use the `util/mongoutils/str.h` library.

**str.h**

`util/mongoutils/str.h` provides string helper functions for each manipulation. Add new functions here rather than lines and lines of code to your app that are not generic.

Typically these functions return a string and take two as parameters : string l(string,string). Thus we wrap them all in a namespace called `str`

`str::stream()` is quite useful:

```cpp
uassert(12345, str::stream() << "bad ns:" << ns, isok);
```

**StringData**

```cpp
/** A StringData object wraps a 'const string6' or a 'const char*' without
 * copying its contents. The most common usage is as a function argument that
 * takes any of the two forms of strings above. Fundamentally, this class tries
 * go around the fact that string literals in C++ are char[N]'s.
 * Note that the object StringData wraps around must be alive while the StringData
 * is.
 */
class StringData {

See also `bson/stringdata.h`.```
MongoUtils

MongoUtils has its own namespace. Its code has these basic properties:

1. Are not database specific, rather, true utilities
2. Are cross platform
3. May require boost headers, but not libs (header-only works with mongoutil)
4. Are clean and easy to use in any C++ project without pulling in lots of other stuff
5. Apache license

Memory management

Overall guidelines

- Avoid using bare pointers for dynamically allocated objects. Prefer scoped_ptr, shared_ptr, or another RAII class such as BSONObj.
- Do not use auto_ptr's and refactor legacy ones out whenever possible. (Careful with C++ driver and backward compatibility though.)
- If you assign the output of new/malloc() directly to a bare pointer you should document where it gets deleted/freed, who owns it along the way, and how exception safety is ensured. If you cannot answer all three questions then you probably have a leak.

Writing tests

We have four general flavors of tests currently.

General guidelines

It is important that tests can be run in parallel and still succeed.
For example, make sure that:

- try to use a unique collection name, for example named after the test

```
t = db.jstests_currentop
```

- If checking on current operations, make sure to add an NS filter

```
db.currentOp({ns: "test.mytest"})
```

- If possible, try to avoid things that are global to mongod or the database (oplog, profiling, fsync)

If the test cannot be run in parallel, add it to the blacklist in “skipTests” in shell/utils.js.

dbtets (Deprecated - avoid adding to this)

Old-style C++ unit tests are in the dbtests/ subfolder. See the code therein. To run:

```
scons test
./test --help
```

Unit tests

New-style C++ unit tests use the Unit Test framework in src/mongo/unittest. The actual unit test files appear in the same subdirectory as the source file being tested.
To run all the tests:

```
scons smokeCppUnitests
```

jstests

Many tests are written as .js scripts that are executed via the mongo shell. See the Smoke Tests link at the bottom for how to run comprehensive sets of tests. To run a particular test:
start mongod first then run a few simple tests:

```
mongo jstests/basic*.js
```

Note there are several subdirectories for different test suites. slowNightly is run by the buildbots only once a night; slowWeekly only once a week. Most other tests are ran every CI cycle (all the time).

Also note that the js tests rely on functions defined in the "shell" directory (see servers.js and util.js in particular).

**lint**

`scons lint` will run `cpplint` with the flags we care about over the entire codebase. This is how buildbot runs lint.

To run lint on an individual file or directory, use `python buildscripts/lint.py src/mongo/platform/`

Use the `--nudge` flag to turn on warnings for rules we may turn on soon.

**Lightweight startup test.**

You can inherit from class `mongo::UnitTest` and make a test that runs at program startup. These tests run EVERY TIME the program starts. Thus, they should be minimal: the test should ideally take 1ms or less to run. Why run the tests in the general program? This gives some validation at program run time that the build is reasonable. For example, we test that pcre supports UTF8 regex in one of these tests at startup. If someone had built the server with other settings, this would be flagged upon execution, even if the test suite has not been invoked. Most tests are not of this sort.

- Smoke Tests
- [http://buildbot.mongodb.org/](http://buildbot.mongodb.org/)

### Project Ideas

If you're interested in getting involved in the MongoDB community (or the open source community in general) a great way to do so is by starting or contributing to a MongoDB related project. Here we've listed some project ideas for you to get started on. For some of these ideas projects are already underway, and for others nothing (that we know of) has been started yet.

#### 10gen Labs

Contribute to a project in 10gen labs, 10gen's incubator for open source MongoDB tools. There are a number of projects that can use the community's input

- Mongo-connector
- Storage-viz for visualizing MongoDB storage and indexes.
- Edda a log visualizer for MongoDB.
- Sleepy Mongoose A REST Interface for MongoDB

#### A GUI

One feature that is often requested for MongoDB is a GUI, much like CouchDB's futon or phpMyAdmin. There are a couple of projects working on this sort of thing that are worth checking out:

- Futon 4 Mongo
- HTTP Interface

We've also started to spec out the features that a tool like this should provide.

#### A REST Interface

There are a number of requests for a REST API for MongoDB. There are a number of existing projects out there that could use contributors

- Sleepy Mongoose a full-feature HTTP Interface for MongoDB
- DrowsyDromedary is a REST layer for Mongo based on Ruby.
- MongoDB Rest (Node.js) is an alpha REST interface to MongoDB, which uses the MongoDB Node Native driver.
- Mongodb Java REST server based on Jetty.

#### Try Mongo!

It would be neat to have a web version of the MongoDB Shell that allowed users to interact with a real MongoDB instance (for doing the tutorial,
A project that does something similar (using a basic MongoDB emulator) is here:

http://github.com/banker/mongulator

Mongoly is another great interactive tutorial by Karl Seguin]

**Real-time Full Text Search Integration**

It would be interesting to try to nicely integrate a search backend like Xapian, Lucene or Sphinx with MongoDB. One idea would be to use MongoDB's oplog (which is used for master-slave replication) to keep the search engine up to date.

**GridFS FUSE**

There is a project working towards creating a FUSE filesystem on top of GridFS - something like this would create a bunch of interesting potential uses for MongoDB and GridFS:

http://github.com/mikejs/gridfs-fuse

**Framework Adaptors**

Working towards adding MongoDB support to major web frameworks is a great project, and work has been started on this for a variety of different frameworks (please use google to find out if work has already been started for your favorite framework).

**Logging and Session Adaptors**

MongoDB works great for storing logs and session information. There are a couple of projects working on supporting this use case directly.  

Logging:
Zend
Python
Rails

Sessions:
web.py
Beaker

**Package Managers**

Add support for installing MongoDB with your favorite package manager and let us know!

**Locale-aware collation / sorting**

MongoDB doesn't yet know how to sort query results in a locale-sensitive way. If you can think up a good way to do it and implement it, we'd like to know!

**Drivers**

If you use an esoteric/new/awesome programming language write a driver to support MongoDB! Again, check google to see what people have started for various languages.

Some that might be nice:

- Scheme (probably starting with PLT)
- GNU R
- Visual Basic
- Lisp (e.g, Common Lisp)
- Delphi
- Falcon

Write a killer app that uses MongoDB as the persistence layer!

**Roadmap**

Please see jira.

**UI**
Spec/requirements for a future MongoDB admin UI.

- list databases
  - repair, drop, clone?
- collections
  - validate(), datasize, indexsize, clone/copy
- indexes
- queries - explain() output
- security: view users, adjust
- see replication status of slave and master
- sharding
- system.profile viewer ; enable disable profiling
- curop / killop support

Source Code

Source for MongoDB and mongodb.org supported drivers is open source and hosted at Github.

- Mongo Database (includes C++ driver)
- Python Driver
- PHP Driver
- Ruby Driver
- Java Driver
- Perl Driver
- C# Driver
- Scala Driver
- Erlang Driver
- Haskell Driver

(Additionally, community drivers and tools also exist and will be found in other places.)

Building

Note: see the Downloads page for prebuilt binaries, it's recommended to use those as all full QA occurs after those are built.

This section provides instructions on setting up your environment to write Mongo drivers or other infrastructure code. For specific instructions, go to the document that corresponds to your setup.

Sub-sections of this section:

- Building Boost
- Building for FreeBSD
- Building for Linux
- Building for OS X
- Building for Solaris
- Building for Windows
- Building Spider Monkey
- Building with V8
- scons

See Also

- The main Database Internals page

Building Boost

NOTE
This is not necessary when building mongo versions 2.1.1 or later.

MongoDB uses the [www.boost.org] C++ libraries.
Windows

See also the prebuilt libraries page.

By default c:\boost\ is checked for the boost files. Include files should be under \boost\boost, and libraries in \boost\lib.

First download the boost source. Then use the 7 Zip utility to extra the files. Place the extracted files in C:\boost.

Then we will compile the required libraries.

See buildscripts/buildboost.bat and buildscripts/buildboost64.bat for some helpers.

```
> rem set PATH for compiler:
> "C:\Program Files (x86)\Microsoft Visual Studio 10.0\VC\vcvarsall.bat"
> 
> rem build the bjam make tool:
> cd \boost\tools\jam\src\ 
> build.bat 
> 
> cd \boost 
> tools\jam\src\bin.ntx86\bjam --help
> rem see also mongo\buildscripts\buildboost*.bat 
> rem build DEBUG libraries: 
> tools\jam\src\bin.ntx86\bjam variant=debug threading=multi --with-program_options --with-filesystem
--with-date_time --with-thread
> mkdir lib 
> move stage\lib\* lib\ 
```

Linux

It's common with linux to install boost via a package manager – see the Building for Linux page for specifics.

However one might also want to build from boost.org sources in some cases, for example to use a newer version of boost, to generate static libraries, etc.

The following – far from comprehensive, rather an example – shows manually building of boost libraries on Linux.

```
$ sudo ./bootstrap.sh 
$ ./b2 --help
$ # now build it
$ ./b2 $ #or
$ ./b2 --with-program_options --with-filesystem --with-date_time --with-thread
$ sudo ./b2 install
```

Troubleshooting

Unresolved external get_system_category() when linking MongoDB
Try defining BOOST_SYSTEM_NO_DEPRECATED in the MongoDB SConstruct file.

Building for FreeBSD

On FreeBSD 8.0 and later, there is a mongodb port you can use.

For FreeBSD <= 7.2:

2. Update your ports tree:

```
$ sudo portsnap fetch && portsnap extract
```

The packages that come by default on 7.2 and older are too old, you'll get weird errors when you try to run the database)
3. Install SpiderMonkey:

```bash
$ cd /usr/ports/lang/spidermonkey && make && make install
```

4. Install scons:

```bash
$ cd /usr/ports/devel/scons && make && make install
```

5. Install boost: (it will pop up an X "GUI", select PYTHON)

```bash
$ cd /usr/ports/devel/boost-all && make && make install
```

6. Install libunwind:

```bash
$ cd /usr/ports/devel/libunwind && make && make install
```

7. Change to the database source directory
8. scons all

- Building for Linux - many of the details there including how to clone from git apply here too.

**Building for Linux**

Note: Binaries are available for most platforms. Most users won’t need to compile mongo themselves; in addition every prebuilt binary has been regression tested. See the Downloads page for these prebuilt binaries.

- Build Prerequisites
  - Fedora
  - Ubuntu

- Building

- Building Older Versions
  - Fedora
  - Ubuntu
    - Ubuntu 8.04 and 8.10
    - Ubuntu 9.04 and Newer

- Building
- Troubleshooting

These instructions apply to the git master branch, and versions 2.1.1 and onward. At the end of the document are instructions for older versions.

**Build Prerequisites**

You’ll need SCons, the gnu C++ toolchain, and glibc-devel. To get the code from github, you’ll probably also want git.

**Fedora**

```bash
sudo yum -y install git-core scons gcc-c++ glibc-devel
```

**Ubuntu**

```bash
sudo apt-get install git-core build-essential scons
```

**Building**

1. Install any needed prerequisites (see above).
2. Get the source code
3. Pick a version to build (only use "master" if you're doing development work).
   a. List all tagged versions
   
   ```bash
   git tag -l
   ```
   
   b. Check out a tagged release, e.g. 2.0.4
   
   ```bash
   git checkout r2.0.4
   ```

4. Compile

   ```bash
   scons all
   ```

5. Install. Use --prefix to specify where you want to install your binaries. Defaults to /usr/local.

   ```bash
   scons --prefix=/opt/mongo install
   ```

Building Older Versions

Fedora

The following steps have been reported to work for Fedora versions from 11 to 16. (If they don't work on newer versions, please report this to mongodb-user@googlegroups.com.) Fedora versions 10 and earlier ship with a version of SCons that is too old to build MongoDB, but may work if you manually install SCons.

```bash
sudo yum -y install git-core scons gcc-c++ glibc-devel
sudo yum -y install boost-devel boost-devel-static
```

Ubuntu

Note: See SpiderMonkey note above.

Use cat /etc/lsb-release to see your version.

**Ubuntu 8.04 and 8.10**

```bash
apt-get -y install git-core build-essential
apt-get -y install libboost-dev libboost-program-options-dev libboost-thread-dev
libboost-filesystem-dev
```

Ubuntu 8.04 and 8.10 ship with a version of SCons that is too old to build MongoDB, but may work if you manually install SCons.

**Ubuntu 9.04 and Newer**

```bash
aptitude install -y git-core build-essential scons
aptitude install -y libboost-dev libboost-program-options-dev libboost-thread-dev
libboost-filesystem-dev
```

Building

1. Install prerequisites
2. get source

```bash
git clone git://github.com/mongodb/mongo.git
cd mongo
# pick a stable version unless doing true dev
git tag -l
# Switch to a stable branch (unless doing development) --
# an even second number indicates "stable". For example:
git checkout r2.0.4
```

3. build

```bash
scons all
```

4. install --prefix can be anywhere you want to contain your binaries, e.g., /usr/local or /opt/mongo.

```bash
scons --prefix=/opt/mongo install
```

Troubleshooting

- Link errors. If link errors occur, the \-t GCC option is useful for troubleshooting. Try adding \-t to the SConstruct file's LINKFLAGS.
- Static libraries. The \--release scons option will build a binary using static libraries. You may need to install static boost libraries when using this option.

Building for OS X

- Prerequisites
  - Xcode
  - SCons
  - git
- Building
- Older Versions of Mongo
  - Upgrading to Snow Leopard
- Setup
  - Sources
  - Prerequisites
  - Package Manager Setup
  - Manual Setup
    - Install Apple developer tools
    - Install libraries (32-bit option)
    - Install libraries (64-bit option)
- Compiling
- Troubleshooting

To set up your OS X computer for MongoDB development:

**Prerequisites**

**Xcode**

Available in the App Store. You only need to get the command line tools, if you don't want to install the whole IDE.

**SCons**

SCons is the build tool used to compile mongo binaries. It is available from [http://www.scons.org](http://www.scons.org).

If you have easy_install or pip already installed, you can use them to install scons.

```bash
easy_install scons
```

```bash
pip install scons
```
git

An installer package is available from http://git-scm.com/

Building

1. Install any needed prerequisites (see above).
2. Get the source code

```
  git clone git://github.com/mongodb/mongo.git
  cd mongo
```

3. Pick a version to build (only use "master" if you're doing development work).
   a. List all tagged versions

```
  git tag -l
```

   b. Check out a tagged release, e.g. 2.0.4

```
  git checkout r2.0.4
```

4. Compile

```
  scons all
```

5. Install. Use --prefix to specify where you want to install your binaries. Defaults to /usr/local.

```
  scons --prefix=/opt/mongo install
```

Older Versions of Mongo

Upgrading to Snow Leopard

If you have installed Snow Leopard, the builds will be 64-bit -- so if moving from a previous OS release, a bit more setup may be required than one might first expect.

Setup

Sources

The mongodb source is on github. To get sources first download the git client and install it.

- Then git clone git://github.com/mongodb/mongo.git (more info)
  Note If you do not wish to install git you can instead get the source code from the Downloads page.

Prerequisites

- Install gcc. Install XCode tools for Snow Leopard. gcc version 4.0.1 (from older XCode Tools install) works, but you will receive compiler warnings. One way to get a newer gcc is to install Command Line Tools for XCode from developer.apple.com.

Package Manager Setup

1. Install Homebrew
2. Update/install dependencies:

```
  brew install boost
```
3. Install SCons:
brew install scons

**Manual Setup**

Install Apple developer tools

Install libraries (32-bit option)

1. Download boost 1.37.0. Apply the following patch:

```diff
diff -u -r a/configure b/configure
--- a/configure 2009-01-26 14:10:42.000000000 -0500

# Install unit test framework http://unittest.red-bean.com/ (optional)

CFLAGS="-m64" CXXFLAGS="-m64" LDFLAGS="-m64" ./configure --prefix /usr/64; make; sudo make install

Compiling

To compile 32-bit, just run:

scons

To compile 64-bit on 10.5 (64 is default on 10.6), run:

scons --64

See the, MongoDB scons page for more details/compile options.

Troubleshooting

- Try not using the scons --release option (if you are using it). That option attempts to use static libraries.
Building for Solaris

MongoDB server currently supports little endian Solaris operation. (Although most drivers – not the database server – work on both.)

Community: Help us make this rough page better please! (And help us add support for big endian please...)

Prerequisites:
- g++ 4.x (SUNWgcc)
- scons (need to install from source)
- spider monkey Building Spider Monkey
- pcre (SUNWpcre)
- boost (need to install from source)

See Also
- Joyent
- Building for Linux - many of the details there including how to clone from git apply here too

Building for Windows

Binaries are available for most platforms. Most users won't need to compile mongo themselves; in addition every prebuilt binary has been regression tested. See the Downloads page for these prebuilt binaries.

MongoDB can be compiled for Windows (32 and 64 bit); You will need to have the platform sdk installed. The platform sdk can be installed manually, and it comes with Visual (Studio) C++ as well. SCons is the make mechanism, although several .vcxprojs and a .sln solution file are also included in the project for convenience when using the Visual Studio 2010 IDE.

There are several dependencies exist which are listed below; you may find it easier to simply download a pre-built binary.

- Building with Visual Studio 2008
- Building with Visual Studio 2010
- Building the Shell

See Also
- Windows Quick Links
- scons

Boost 1.41.0 Visual Studio 2010 Binary

This is OLD and was for the VS2010 BETA. See the new Boost and Windows page instead.

The following is a prebuilt boost binary (libraries) for Visual Studio 2010 beta 2.

The MongoDB vcxproj files assume this package is unzipped under c:\Program Files\boost\boost_1_41_0\.

- http://downloads.mongodb.org/misc/boost_1_41_0_binary_vs10beta2.zipx

Note: we're not boost build gurus please let us know if there are things wrong with the build.

See also the prebuilt boost binaries at http://www.boostpro.com/download.

Boost and Windows

- Visual Studio 2010
  - Prebuilt from mongodb.org
  - Building Yourself
- Visual Studio 2008
  - Prebuilt from mongodb.org
  - Prebuilt from boostpro.com
  - Building Yourself
- Additional Notes
Visual Studio 2010

Prebuilt from mongodb.org

Click here for a prebuilt boost library for Visual Studio 2010. 7zip format.

Building Yourself

- Download the boost source from boost.org. Move it to C:\boost\.
- We have successfully compiled version 1.42 – you might want to try that version or higher, but not 1.45 or later. 1.45 changed the interface to the boost::filesystem library and we’ve yet to catch up. See additional notes section at end of this page too.
- Run C:\Program Files (x86)\Microsoft Visual Studio 10.0\vc\vcvarsall.bat.
- From the MongoDB source project, run buildscripts\buildboost.bat. Or, buildboost64.bat for the 64 bit version.

Visual Studio 2008

Prebuilt from mongodb.org

Click here for a prebuilt boost library for Visual Studio 2008. 7zip format. This file has what you need to build MongoDB, but not some other boost libs, so it’s partial.

Prebuilt from boostpro.com

Or, you can download a complete prebuilt boost library for 32 bit VS2008 at http://www.boostpro.com/products/free. Install the prebuilt libraries for Boost version 1.35.0 (or higher - generally newer is better). During installation, for release builds choose static multithread libraries for installation. The Debug version of the project uses the DLL libraries; choose all multithread libraries if you plan to do development. From the BoostPro installer, be sure to select all relevant libraries that mongodb uses -- for example, you need Filesystem, Regex, Threads, and ProgramOptions (and perhaps others).

Building Yourself

- Download the boost source from boost.org. Move it to C:\boost\.
- From the Visual Studio 2008 IDE, choose Tools:Visual Studio Command Prompt to get a command prompt with all PATH variables set nicely for the C++ compiler.
- From the MongoDB source project, run buildscripts\buildboost.bat. Or, buildboost64.bat for the 64 bit version.

Additional Notes

When using bjam, MongoDB expects

- variant=debug for debug builds, and variant=release for release builds
- threading=multi
- link=static runtime-link=static for release builds
- address-model=64 for 64 bit

Building the Mongo Shell on Windows

You can build the mongo shell with either scons or a Visual Studio 2010 project file.

Scons

```
scons mongo.exe
```

Visual Studio 2010 Project File

A VS2010 vcxproj file is available for building the shell. From the mongo directory open shell\msvc\mongo.vcxproj.

The project file currently only supports 32 bit builds of the shell (scons can do 32 and 64 bit). However this seems sufficient given there is no real need for a 64 bit version of the shell.

Building with Visual Studio 2008
NOTE

These instructions are for versions of mongo prior to 2.1.1. For version 2.1.1 and newer, the instructions for Visual Studio 2010 and Visual Studio 2008 are the same.

- Get the MongoDB Source Code
- Get Boost Libraries
- Get SpiderMonkey
- Install SCons
- Building MongoDB with SCons
- Troubleshooting

MongoDB can be compiled for Windows (32 and 64 bit) using Visual C++. SCons is the make mechanism we use with VS2008. (Although it is possible to build from a sln file with vs2010.)

There are several dependencies exist which are listed below; you may find it easier to simply download a pre-built binary.

**Get the MongoDB Source Code**

Download the source code from Downloads.

Or install Git. Then:

- `git clone git://github.com/mongodb/mongo.git` *(more info)*
- `git tag -l` to see tagged version numbers
- Switch to a stable branch (unless doing development) -- an even second number indicates "stable". (Although with sharding you will want the latest if the latest is less than 1.6.0.) For example:
  - `git checkout r1.4.1`

**Get Boost Libraries**

- Click here for a prebuilt boost library for Visual Studio. 7zip format. This file has what you need to build MongoDB, but not some other boost libs, so it's partial.
- See the Boost and Windows page for other options.

The Visual Studio project files are setup to look for boost in the following locations:

- `c:\program files\boost\latest`
- `c:\boost`
- `\boost`

You can unzip boost to `c:\boost`, or use an NTFS junction point to create a junction point to one of the above locations. Some versions of windows come with linkd.exe, but others require you to download Sysinternals' junction.exe to accomplish this task. For example, if you installed boost 1.42 via the installer to the default location of `c:\Program Files\boost\boost_1_42`, You can create a junction point with the following command:

```
junction "c:\Program Files\boost\latest" "c:\Program Files\boost\boost_1_42"
```

This should return the following output:

```
Junction v1.05 - Windows junction creator and reparse point viewer
Copyright (C) 2000-2007 Mark Russinovich
Systems Internals - http://www.sysinternals.com

Created: c:\Program Files\boost\latest
Targetted at: c:\Program Files\boost\boost_1_42
```

**Get SpiderMonkey**

Build a SpiderMonkey js engine library (js.lib) – details here.

**Install SCons**
If building with scons, install SCons:

- First install Python: [http://www.python.org/download/releases/2.6.4/](http://www.python.org/download/releases/2.6.4/).
- Then SCons itself: [http://sourceforge.net/projects/scons/files/scons/1.2.0/scons-1.2.0.win32.exe/download](http://sourceforge.net/projects/scons/files/scons/1.2.0/scons-1.2.0.win32.exe/download).
- Add the python scripts directory (e.g., C:\Python26\Scripts) to your PATH.

**Building MongoDB with SCons**

The SConstruct file from the MongoDB project is the preferred way to perform production builds. Run scons in the mongo project directory to build.

If scons does not automatically find Visual Studio, preset your path for it by running the VS2010 vcvars*.bat file.

To build:

```bash
scons  // build mongod
scons mongoclient.lib  // build C++ client driver library
scons all  // build all end user components
scons .  // build all including unit test
```

**Troubleshooting**

- **If you are using scons**, check the file `config.log` which is generated.

- **Can't find jstypes.h when compiling.** This file is generated when building SpiderMonkey. See the [Building SpiderMonkey](#) page for more info.
- **Can't find / run cl.exe when building with scons.** See troubleshooting note on the [Building SpiderMonkey](#) page.

**Building with Visual Studio 2010**

- **v2.1.1+**
  - Get the MongoDB Source Code
  - Building MongoDB from the IDE
  - Building with SCons
  - Troubleshooting
- **Older versions**
  - Get the MongoDB Source Code
  - Get Boost Libraries
  - Get SpiderMonkey
  - Building MongoDB from the IDE
  - Install SCons
  - Troubleshooting

- **v2.1.1+**

MongoDB can be compiled for Windows (32 and 64 bit) using Visual C++. SCons is the make mechanism, although a solution file is also included in the project for convenience when using the Visual Studio IDE. (These instructions don’t work using Visual Studio Express, which must be uninstalled to get Visual Studio Professional/Ultimate to work properly; VSE can only do 32 bit builds.)

These instructions are for mongo versions 2.1.1 and later.

**Get the MongoDB Source Code**

Download the source code from [Downloads](#).

Or install Git. Then:

- `git clone git://github.com/mongodb/mongo.git` [more info]
- `git tag -l` to see tagged version numbers
- Switch to a stable branch (unless doing development) -- an even second number indicates "stable". For example:
  - `git checkout r1.4.1`
Building MongoDB from the IDE

Open the db\db_10.sln solution file.

Note: a separate project file exists for the mongo shell. Currently the C++ client libraries must be built from scons (this obviously needs to be fixed...)

Building with SCons

1. Install SCons:
   a. First install Python: http://www.python.org/download/releases/2.7.2/.
      • Note Make sure to install the 32 bit version of python and not the 64 bit as the scons binaries below are 32 bit.
   b. It is recommended you install pywin32 if you want to do parallel builds (scons -j).
   d. Add the python scripts directory (e.g., C:\Python27\Scripts) to your PATH.

1. Build:

   ```
scons // build mongod
scons --release mongoclient.lib // build C++ client driver library
scons --release core // build all end user components
   ```

Add --64 or --32 to get the 64 and 32-bit versions, respectively. Replace --release with --dd to build a debug build.

Troubleshooting

If you are using scons, check the file config.log which is generated.

If scons does not automatically find Visual Studio, try using the Visual Studio Command Prompt, which will set your path for you. Alternatively, set your path manually by running the VS2010 vcvars.bat files. Location may vary with install but usually it is something like:

- C:\Program Files (x86)\Microsoft Visual Studio 10.0\Common7\Tools\vsvars32.bat
- C:\Program Files (x86)\Microsoft Visual Studio 10.0\VC\bin\amd64\vcvars64.bat

Older versions

The following instructions are for versions of mongo prior to 2.1.1.

There are several dependencies exist which are listed below; you may find it easier to simply download a pre-built binary.

Get the MongoDB Source Code

Download the source code from Downloads.

Or install Git. Then:

- `git clone git://github.com/mongodb/mongo.git` (more info)
- `git tag -l` to see tagged version numbers
- Switch to a stable branch (unless doing development) -- an even second number indicates “stable”. (Although with sharding you will want the latest if the latest is less than 1.6.0.) For example:
  - `git checkout r1.4.1`

Get Boost Libraries

- Click here for a prebuilt boost library for Visual Studio. 7zip format. This file has what you need to build MongoDB, but not some other boost libs, so it’s partial. Uncompress this to the c:\boost directory. Your actual files are in c:\boost\boost
- See the Boost and Windows page for other options. Use v1.42 or higher with VS2010.

Get SpiderMonkey

- Download prebuilt libraries and headers here for VS2010. Place these files in ..\js\ relative to your mongo project directory.
- Or (more work) build SpiderMonkey js.lib yourself -- details here.

Building MongoDB from the IDE
Open the db/db_10.sln solution file.

Note: a separate project file exists for the mongo shell. Currently the C++ client libraries must be built from scons (this obviously needs to be fixed...)

**Install SCons**

If building with scons, install SCons:

- First install Python: [http://www.python.org/download/releases/2.7.2/](http://www.python.org/download/releases/2.7.2/).
  - **Note** Make sure to install the 32 bit version of python and not the 64 bit as the scons binaries below are 32 bit.
- Add the python scripts directory (e.g., C:\Python27\Scripts) to your PATH.

The SConstruct file from the MongoDB project is the preferred way to perform production builds. Run scons in the mongo project directory to build.

If scons does not automatically find Visual Studio, preset your path for it by running the VS2010 vsvars*.bat files. Location may vary with install but usually it is something like:

- C:\Program Files (x86)\Microsoft Visual Studio 10.0\Common7\Tools\vsvars32.bat
- C:\Program Files (x86)\Microsoft Visual Studio 10.0\VC\bin\amd64\vcvars64.bat

To build:

```
  scons               // build mongod
  scons mongoclient.lib // build C++ client driver library
  scons all           // build all end user components
  scons .             // build all including unit tests and C++ driver zip file
  scons --64          // build the 64 bit version
  scons --dd           // build with debug symbols
  scons -jX            // perform X steps in parallel (e.g. -j16 will compile 16 files at once)
```

**Troubleshooting**

- Can’t find jstypes.h when compiling.
  - This file is generated when building SpiderMonkey. See the Building SpiderMonkey page for more info.
- Can’t find / run cl.exe when building with scons.
  - Be sure to use Visual Studio Command Prompt so that your path is set correctly.
  - LINK fatal error LNK1104: cannot open file js64d.lib js64r.lib js32d.lib js32r.lib
  - Get the prebuilt spidermonkey libraries -- or copy your self-built js.lib to the above name.
  - You can also see this if you’re using the wrong compiler; this is the result if you try to use Visual Studio Express instead of Visual Studio Professional/Ultimate, which is a different product.

**Building Spider Monkey**

- Building js.lib - Unix
  - Remove any existing xulrunner
  - Download
  - Build
  - Install
- Building js.lib - Windows
  - Prebuilt
  - Download
  - Build
  - Troubleshooting scons

*See Also*

MongoDB uses SpiderMonkey for server-side Javascript execution.

Pre v2.0: MongoDB requires a js.lib file when linking. This page details how to build js.lib.

v2.0+: this is handled automatically by the Mongo build scripts via files under third_party/ in the MongoDB project directory.
Note: V8 Javascript support is under development.

Building js.lib - Unix

Remove any existing xulrunner

First find out what has been installed

```bash
dpkg -l | grep xulrunner
```

E.g.

```
ubuntu910-server64:mongo$ sudo dpkg -l | grep xul
ii  xulrunner-1.9.1                   1.9.1.13+build1+nobinonly-0ubuntu0.9.10.1 XUL + XPCOM
application runner
ii  xulrunner-1.9.1-dev               1.9.1.13+build1+nobinonly-0ubuntu0.9.10.1 XUL + XPCOM
development files
```

Next remove the two installed packages

```bash
sudo apt-get remove xulrunner-1.9.1-dev xulrunner-1.9.1
```

Download

```bash
curl -O ftp://ftp.mozilla.org/pub/mozilla.org/js/js-1.7.0.tar.gz
tar zxvf js-1.7.0.tar.gz
```

Build

```bash
cd js/src
export CFLAGS="-DJS_C_STRINGS_ARE_UTF8"
make -f Makefile.ref
```

SpiderMonkey does not use UTF-8 by default, so we enable before building.

An experimental SConstruct build file is available [here](#).

Install

```bash
JS_DIST=/usr make -f Makefile.ref export
```

By default, the mongo scons project expects spidermonkey to be located at `../js/`.

Building js.lib - Windows

Prebuilt

- VS2008: a prebuilt SpiderMonkey library and headers for Win32 is attached to this document (this file may or may not work depending on your compile settings and compiler version).
- VS2010 prebuilt libraries (js64d.lib, etc.)

Alternatively, follow the steps below to build yourself.

Download

From an `msysgit` or cygwin shell, run:
Build

cd js/src

```
export CFLAGS="-DJS_C_STRINGS_ARE_UTF8"
make -f Makefile.ref
```

If `cl.exe` is not found, launch Tools...Visual Studio Command Prompt from inside Visual Studio -- your path should then be correct for make.

If you do not have a suitable make utility installed, you may prefer to build using scons. An experimental SConstruct file to build the js.lib is available in the mongodb/snippets project. For example:

```
cd
git clone git://github.com/mongodb/mongo-snippets.git
cp mongo-snippets/jslib-sconstruct js/src/SConstruct
cd js/src
scons
```

Troubleshooting scons

Note that scons does not use your PATH to find Visual Studio. If you get an error running cl.exe, try changing the following line in the msvc.py scons source file from:

```
MVSdir = os.getenv('ProgramFiles') + r'\Microsoft Visual Studio 8'
```

to

```
MVSdir = os.getenv('ProgramFiles') + r'\Microsoft Visual Studio ' + version
```

See Also

- Building MongoDB

Building with V8

Linux or OSX

```
$ pwd
~/mongo
$ cd ..
$ svn checkout http://v8.googlecode.com/svn/trunk/ v8
$ cd v8
$ scons arch=x64 debuggersupport=off snapshot=off profilingsupport=off
$ cd ../mongo
$ scons --usev8
```

Windows
$ pwd
~/mongo
$ cd ..
$ svn checkout http://v8.googlecode.com/svn/trunk/ v8
$ cd v8
$ scons env="PATH:%PATH%,INCLUDE:%INCLUDE%,LIB:%LIB%" arch=x64
$ cd ../mongo
$ scons --usev8 --release --64

**scons**

Use scons to build MongoDB and related utilities and libraries. See the SConstruct file for details.

Run scons --help to see all options.

**Targets**

Run scons <target>.

- `scons all`
- `scons mongod` build mongod (this is the default target if none is specified)
- `scons mongo` build the shell
- `scons mongoclient` build just the client library (builds libmongoclient.a on Unix)
- `scons test` build the unit test binary test

**Options**

- `--d` debug build; all this does is turns optimization off
- `--dd` debug build with _DEBUG defined (extra asserts, checks, etc.)
- `--release`
- `--32` force 32 bit
- `--64` force 64 bit
- `--clean` cleans the target specified
- `--mute` suppress compile and link command lines

**Troubleshooting**

scons generates a `config.log` file. See this file when there are problems building.

**See Also**

Smoke Tests

**Database Internals**

This section provides information for developers who want to write drivers or tools for MongoDB, contribute code to the MongoDB codebase itself, and for those who are just curious how it works internally.

Sub-sections of this section:

- Durability Internals
- Parsing Stack Traces
- Error Codes
- Replication Internals
- Smoke Tests
- Pairing Internals

**Durability Internals**

⚠️ The main durability page (not the internals page) is the Journaling page.
Files

The data file format is unchanged.

Journal files are placed in /data/db/journal/.

Running

Journaling is on by default. Run with --nojournal to disable journaling/durable storage. Both mongod and test support this option.

Declaring Write Intent

When writing mongod kernel code, one must now declare an intention to write. Declaration of the intent occurs before the actual write. See db/dur.h. The actual write must occur before releasing the write lock.

When you do your actual writing, use the pointer that dur::writing() returns, rather than the original pointer.

```c
Foo *foo;
getDur().writing(thing)->bar = something;

int *x;
getDur().writingInt(x) += 3;

DiskLoc &loc;
loc.writing() = newLoc;

void *p;
unsigned len;
memcpy( getDur().writingPtr(p,len), src, len );
```

Try to declare intent on as small a region as possible. That way less information is journalled. For example

```c
BigStruct *b;
dur::writing(b)->x = 3; // less efficient
*dur::writing(&b->x) = 3; // more efficient
```

However, there is some overhead for each intent declaration, so if many members of a struct will be written, it is likely better to just declare intent on the whole struct.

Tests

jstests/dur/ contains tests for durability.

```bash
mongo --nodb jstests/dur/<testname>.js
```

Administrative
dump journal entries during any recover, and then start normally
mongod --journal --durOptions 1

dump journal entries (doing nothing else) and then terminate
mongod --journal --durOptions 7

extra checks that everything is correct (slow but good for qa)
mongod --journal --durOptions 8

Diagrams

- diagram 1 - process steps
- diagram 2 - journal file structure

Parsing Stack Traces

`addr2line`

```
addr2line -e mongod -ifC <offset>
```

`c++filt`

You can use `c++filt` to demangle function names by pasting the whole stack trace to stdin.

**Finding the right binary**

To find the binary you need:

- Get the commit at the header of any of our logs.
- Use git to locate that commit and check for the surrounding "version bump" commit

Download and open the binary:

```
$ curl -O http://s3.amazonaws.com/downloads.mongodb.org/linux/mongodb-linux-x86_64-debugsymbols-1.x.x.tgz
```

You can also find debugsymbols for official builds by clicking "list" on the Downloads page.

**Example 1**

Then, the log has lines like this:

```
/home/abc/mongod(_ZN5mongo15printStackTraceERSo+0x27) [0x689280]
```

You want the address in between the brackets [0x689280]

Note you will get more than one stack frame for the address if the code is inlined.

**Example 2**

Actual example from a v1.8.1 64 bit linux build:
```bash
$ curl http://downloads.mongodb.org/linux/mongodb-linux-x86_64-debugsymbols-1.8.1.tgz > out.tgz
$ tar -xzf out.tgz
$ cd mongodb-linux-x86_64-debugsymbols-1.8.1/
$ cd bin
$ addr2line --help
$ addr2line -i -e mongod 0x6d6a74
/mnt/home/buildbot/slave/Linux_64bit_V1.8/mongo/db/repl/health.cpp:394
$ addr2line -i -e mongod 0x6d0694
/mnt/home/buildbot/slave/Linux_64bit_V1.8/mongo/db/repl/rs.h:385
/mnt/home/buildbot/slave/Linux_64bit_V1.8/mongo/db/repl/replset_commands.cpp:111
```

### Error Codes

If you have an error event and it isn't obvious what the error is, query for that error code on [Jira](https://jira.mongodb.org). If still nothing please post to support forums.

This list is HIGHLY incomplete. This page is a stub.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>10003</td>
<td>objects in a capped ns cannot grow</td>
<td></td>
</tr>

<td>Fixed in v2.0. Report if seen v2.0+</td>
</tr>
<tr>
<td>13440</td>
<td>bad offset accessing a datafile</td>
<td>Run a database --repair. If journaling is on this shouldn't happen.</td>
</tr>
</tbody>
</table>

### Replication Internals

On the master mongod instance, the local database will contain a collection, oplog.$main, which stores a high-level transaction log. The transaction log essentially describes all actions performed by the user, such as "insert this object into this collection." Note that the oplog is not a low-level redo log, so it does not record operations on the byte/disk level.

The slave mongod instance polls the oplog.$main collection from master. The actual query looks like this:

```javascript
local.oplog.$main.find({ ts: { $gte: 'last_op_processed_time' } }).sort({$natural:1});
```

where 'local' is the master instance's local database. oplog.$main collection is a capped collection, allowing the oldest data to be aged out automatically.

See the Replication section of the [Mongo Developers' Guide](https://docs.mongodb.com/manual/core/replication/) for more information.

### OpTime

An OpTime is a 64-bit timestamp that we use to timestamp operations. These are stored as Javascript Date datatypes but are not JavaScript Date objects. Implementation details can be found in the OpTime class in repl.h.

### Applying OpTime Operations

Operations from the oplog are applied on the slave by reexecuting the operation. Naturally, the log includes write operations only.

Note that inserts are transformed into upserts to ensure consistency on repeated operations. For example, if the slave crashes, we won't know...
exactly which operations have been applied. So if we’re left with operations 1, 2, 3, 4, and 5, and if we then apply 1, 2, 3, 4, 5, we should achieve the same results. This repeatability property is also used for the initial cloning of the replica.

**Tailing**

After applying operations, we want to wait a moment and then poll again for new data with our `gte` operation. We want this operation to be fast, quickly skipping past old data we have already processed. However, we do not want to build an index on `ts`, as indexing can be somewhat expensive, and the oplog is write-heavy. Instead, we use a table scan in natural order, but use a tailable cursor to "remember" our position. Thus, we only scan once, and then when we poll again, we know where to begin.

**Initiation**

To create a new replica, we do the following:

```c
    t = now();
    cloneDatabase();
    end = now();
    applyOperations(t..end);
```

`cloneDatabase` effectively exports/imports all the data in the database. Note the actual "image" we will get may or may not include data modifications in the time range `(t..end)`. Thus, we apply all logged operations from that range when the cloning is complete. Because of our repeatability property, this is safe.

See class `Cloner` for more information.

**Smoke Tests**

- Test Organization
- Running all the tests
- `smoke.py`
- Running a `jstest` manually
- Running the C++ unit tests
- See Also

**Test Organization**

1. `dbs/*.cpp` has C++ unit tests
2. `jstests/*.js` has core tests
3. `jstests/repl/*.js` has replication tests
4. `jstests/sharding/*.js` has sharding tests
5. `slowNightly/*.js` has tests that take longer and run only at night
6. `slowWeekly/*.js` has tests that take even longer and run only once a week

**Running all the tests**

```bash
    scons smoke smokeCppUnitTests smokeDisk smokeTool smokeAuth startMongod smokeClient smokeJs
    scons startMongodSmallOplog smokeJs
    scons startMongod smokeJsSlowNightly
    scons smokeTool
    scons smokeReplSets
    scons smokeRepl smokeClone
    scons smokeDur
    scons mongosTest smokeSharding
    scons smokeRepl smokeClone
    scons startMongod smokeParallel
```

**smoke.py**

`smoke.py` lets you run a subsets of the tests in `jstests/`. When it is running tests, it starts up an instance of mongod, runs the tests, and then shuts it down again. You can run it while running other instances of MongoDB on the same machine: it uses ports in the 30000 range and its own data directories.

For the moment, `smoke.py` must be run from the top-level directory of a MongoDB source repository. This directory must contain at least the `mongo` and `mongod` binaries. To run certain tests, you’ll also need to build the tools and `mongos`. It's a good idea to run `scons .` before running the tests.
To run smoke.py you'll need a recent version of PyMongo.

To see the possible options, run:

```bash
$ python buildscripts/smoke.py --help
Usage: smoke.py [OPTIONS] ARGS

Options:
-h, --help            show this help message and exit
--mode=MODE           If "files", ARGS are filenames; if "suite", ARGS are sets of tests (suite)
--test-path=TEST_PATH Path to the test executables to run, currently only used for 'client' (none)
--mongod=MONGOD_EXECUTABLE Path to mongod to run (/Users/mike/10gen/mongo/mongod)
--port=MONGOD_PORT    Port the mongod will bind to (32000)
--mongo=SHELL_EXECUTABLE Path to mongo, for.js test files (/Users/mike/10gen/mongo/mongo)
--continue-on-failure If supplied, continue testing even after a test fails
--from-file=FILE      Run tests/suites named in FILE, one test per line, '-' means stdin
--smoke-db-prefix=SMOKE_DB_PREFIX Prefix to use for the mongods' dbpaths ('')
--small-oplog         Run tests with master/slave replication & use a small oplog

By default, smoke.py will run tests that create data in /data/db, which may interfere with other MongoDB instances you are running. To change the directory in which the smoke tests create databases, use --smoke-db-prefix=/some/other/path

To run specific tests, use the --mode=files option:

```bash
python buildscripts/smoke.py --mode=files jstests/find1.js
```

You can specify as many files as you want.

You can also run a suite of tests. Suites are predefined and include:

- test
- all
- perf
- js
- quota
- jsPerf
- disk
- jsSlowNightly
- jsSlowWeekly
- parallel
- clone
- repl (master/slave replication tests)
- replSets (replica set tests)
- auth
- sharding
- tool
- client
- mongosTest

To run a suite, specify the suite's name:

```bash
python buildscripts/smoke.py js
```

---

**Running a jstest manually**
You can run a jstest directly from the shell, for example:

```
mongo --nodb jstests/replsets/replsetarb3.js
```

**Running the C++ unit tests**

The tests under jstests/ folder are written in mongo shell javascript. However there are a set of C++ unit tests also. To run them:

```
scons test
./test
```

Build the unit tests (in src/mongo/unittest/) by running:

```
$ scons build/unittests.txt
/* build output */
Generating build/unittests.txt
   build/linux2/dd/durableDefaultOff/mongo/platform/atomic_word_test
   ...
   build/linux2/dd/durableDefaultOff/mongo/bson_template_evaluator_test
   build/linux2/dd/durableDefaultOff/mongo/balancer_policy_test
scons: done building targets.
```

Then use the line above to run the binary generated:

```
$ ./build/linux2/dd/durableDefaultOff/mongo/platform/atomic_word_test
```

**See Also**

- `scons`

**Pairing Internals**

*Policy for reconciling divergent oplogs*

- `pairing is deprecated`

In a paired environment, a situation may arise in which each member of a pair has logged operations as master that have not been applied to the other server. In such a situation, the following procedure will be used to ensure consistency between the two servers:

1. The new master will scan through its own oplog from the point at which it last applied an operation from it's peer's oplog to the end. It will create a set C of object ids for which changes were made. It will create a set M of object ids for which only modifier changes were made. The values of C and M will be updated as client operations are applied to the new master.
2. The new master will iterate through its peer's oplog, applying only operations that will not affect an object having an id in C.
3. For any operation in the peer's oplog that may not be applied due to the constraint in the previous step, if the id of the of the object in question is in M, the value of the whole object on the new master is logged to the new master's oplog.
4. The new slave applies all operations from the new master's oplog.

**Emacs tips for MongoDB work**

You can edit confluence directly from emacs:

First, follow the basic instructions on [http://code.google.com/p/confluence-el/](http://code.google.com/p/confluence-el/)

Change the confluence-url in their sample setup to [http://mongodb.onconfluence.com/rpc/xmlrpc](http://mongodb.onconfluence.com/rpc/xmlrpc)

Might also want to change the default space to DOCS or DOCS-ES or whatever space you edit the most.
etags setup (suggested by mstearn)

First, install "exuberant ctags", which has nicer features than GNU etags.

http://ctags.sourceforge.net/

Then, run something like this in the top-level mongo directory to make an emacs-style TAGS file:

```
ctags -e --extra=qf --fields=i,snfKtm --c++kinds=p --recurse .
```

Then you can use M-x visit-tags-table, M-., M-* as normal.

Technical Support

See the Support page, free support is available and its usage encouraged!

Bug/Feature Tracker (Jira)

File, track, and vote on bugs and feature requests. There is issue tracking for MongoDB and all supported drivers.

Blog

http://blog.mongodb.org/

Mailing List

http://groups.google.com/group/mongodb-announce - for release announcement and important bug fixes.

Events

The events page includes information about MongoDB conferences, webcasts, users groups, local meetups, and open office hours.

Job Board

- Click Here to access the Job Board. The Board is a community resource for all employers to post MongoDB-related jobs. Please feel free to post/investigate positions!
- See also the Indeed MongoDB jobs list

Twitter etc.
Store

- Visit the MongoDB store on Cafepress.

Resources for Driver and Database Developers

Source

The source code for the database and drivers is available at the http://github.com/mongodb.

Developer List

This mongodb-dev mailing list is for people developing drivers and tools, or who are contributing to the MongoDB codebase itself.

Project Ideas

Start or contribute to a MongoDB-related project.

The MongoDB Masters

(sorted alphabetically by last name)

Roman Alexis Anastasini

Roman is a Scala and C# Developer based in Beijing. Originally from Germany, he was formerly a Technical Manager at Gameforge in Kahlsrue Germany. He's now excited to encounter new adventures in Beijing.

- @foliba on Twitter

Katia Aresti

- @KAresti on Twitter
- GitHub

Katia has worked in IT since 2005, first as a consultant at Xebia and Sopra, and as a freelancer since September 2012. She's mostly Java developer (while also dabbling in PHP). She has worked with MongoDB since 2010, becoming one of the first java teams getting MongoDB in production in France, urban dive. She's spoken about Java and MongoDB at Java User Groups, MongoDays and MongoDB User groups about her expertise via hands-on workshops, presentations and open space Q-A’s. One of her ventures is Duchess France, which focuses on educating women developers on emerging technologies. She is passionate about Open Source and enjoys getting involved on community contributions.

MongoDB Contributions

- JDuchess France
- Paris MongoDB User Group

Peter Bell

Peter is Senior VP Engineering and Senior Fellow at General Assembly, a campus for technology, design, and entrepreneurship. He's a regular presenter at national and international conferences on ruby, nodejs, NoSQL (especially MongoDB and neo4j), cloud computing, software craftsmanship, java, groovy, javascript, and requirements and estimating. He is on the program committee for Code Generation in Cambridge, England and the Domain Specific Modeling workshop at SPLASH (was ooPSLA) and reviews and shepherds proposals for the BCS SPA conference.

- Github

Rick Copeland

Rick Copeland is a Lead Software Engineer at SourceForge where he joined the team that introduced MongoDB to the SourceForge technology stack with the migration of the consumer-facing pages of SourceForge from a PHP/relational database platform to Python/MongoDB. Out of that experience came Ming, an MongoDB object/document mapper for Python that he maintains and continues to develop. Rick also helped lead the effort to rewrite the developer tools (wiki, tickets, forums, repos, etc.) portion of the SourceForge site on the Python/MongoDB platform and
released that platform as Allura under the Apache License. He also created the Zarkov realtime analytics framework (also released under the Apache license) used at SourceForge to calculate project statistics. He is a frequent speaker at MongoDB events and an avid MongoDB enthusiast.

- Zarkov, a realtime analytics framework using MongoDB
- Allura, the new MongoDB-powered platform for SourceForge

**Justin Dearing**

Justin Dearing has been working in IT in 2002. He started his career as a night shift AS/400 operator and rose through the ranks at a series of companies.

Justin has worked in both the development and production side of the house on Windows, Unix and Midrange Platforms. Besides MongoDB his database experience includes MySQL, Postgres and Microsoft SQL server. These days he mainly programs in C#, Powershell and PHP.

Justin's life was forever changed on 2009-10-27 when Kristinia Chodorow presented a talk on mongodb at NYPHP and destroyed everything he knew to be right, holy and true about databases. A few months later he push a small app using MongoDB to production. In addition to afflicting the world with apps that use MongoDB, he has contributed to the core server and the official .NET driver.

Justin lives in Jersey City with his wife and 3 laptops.

**Kenny Gorman**

Kenny Gorman has over a decade of experience with various database platforms behind some of the busiest websites in the world. He has had roles as Developer, DBA, Architect, Manager and Director. He was an early adopter of MongoDB in 2009 using it for various projects at Shutterfly. He wrote an early python version of the Mongostat tool that is distributed with MongoDB today. He enjoys performance tuning, large scale systems development, and tricky database problems.

GitHub
Contributions
Wrote the original mongostat in python, since then it's moved to core distribution.

Jonas Haag
Jonas Haag is a passionate Python programmer and free software enthusiast from Stuttgart, Germany. He maintains Django MongoDB Engine, a MongoDB backend for the Python Web framework Django.

MongoDB Contributions

Django MongoDB Engine
PyMongo

Nathen Harvey
Nathen Harvey is a Technical Community Manager at Opscode, the company behind Chef. Nathen is the co-organizer of the Washington DC MongoDB Users' Group and DevOpsDC and co-host of the Food Fight Show, a podcast about Chef and DevOps. Like many others who blog, Nathen updates his blog on a very irregular basis. When not working or hosting meetups, Nathen enjoys going to concerts, drinking craft beer, and over sharing on sites like twitter, untappd, and foursquare.

MongoDB in Production: Data and Availability, March NYC MongoDB User Group

Jon Hoffman
Jon is a software engineer and currently runs the infrastructure engineering team at foursquare. His team is tasked with designing the backends of new features, building robust systems to keep the platform running smoothly and helping other engineers get things done. In the course of his tenure at foursquare Jon has made contributions to the mongoDB's core server, mongo-java-driver, Lift Framework, and scalaj-http projects. Jon recently presented work the foursquare infrastructure team built to add robustness to mongo on top of unreliable disk. Before foursquare Jon spent a brief time working at a three person startup, built distributed systems at Goldman Sachs, worked on VoIP apps for the telephone company, created a medical record app for palm pilot, and graduated from Carnegie Mellon.

Mitch Pirtle

Mitch is currently CTO at Sounday Music, a social and services platform catering to the music industry. There he maintains the core platform comprised of MongoDB and the Lithium framework for PHP.

He was first corrupted by Dwight Merriman while launching Jetsetter for Gilt Groupe, which went on to be the first e-commerce site powered by MongoDB. He then followed that up by launching Totsy, the first e-commerce site to rely solely on MongoDB for all data storage. He is also an original core member for the Mambo content management system, where he went on to found Joomla! and Open Source Matters. Before that he was contributing to many open source projects, and was an outspoken advocate for PostgreSQL, which still remains his favorite relational database.

He is based in Turin Italy with his wife, kids, and rapidly proliferating devices.

Tony is a San Francisco Bay Area native. He received his undergraduate degree in Mechanical Engineering from UC Santa Barbara and his MBA from Santa Clara University. He is currently the CEO of Wordnik. He was the founding engineer and SVP of Engineering at Think Passenger, the leading provider of customer collaboration software. Prior to joining Passenger, he was lead engineer at Composite Software of San Mateo, California. At Composite Software he helped developed the company's first- and second-generation query processing engines and led the research and implementation of their patented cost-based federated query optimizer. Prior to that he led software development in the bioinformatics group at Galileo Labs, a drug-discovery company based in the Silicon Valley.

Rose Toomey

Rose Toomey is the creator of Salat, a simple serialization for Scala and MongoDB
Salat was developed to make using Scala with Casbah and MongoDB as simple as possible. While Casbah increased the usability of the mongo-java-driver in Scala, there was no correspondingly elegant solution for serializing and deserializing objects. The new horizons opened up by using MongoDB as a document store demanded something better than the complexity and ceremony of the ORMs I’d worked with in the past. I also faced the challenge that my company, Novus Partners, is a financial startup that needs to process massive amounts of data very quickly. What to do? Enter Salat: it not only serializes to and from Mongo documents quickly, but uses hi-fi type information provided by the Scala compiler instead of explicit mappings. No fuss, no muss: my goal is that someone who wants to use Scala and MongoDB can be up and running with Salat in fifteen minutes.

MongoDB Master Summit

Since 2011, 10gen has hosted an annual summit for the MongoDB Masters the day before MongoSV.

Notes from 2012 MongoDB Masters Summit

- A MongoDB Masters Book
- ODM Breakout Session
- Schema Design Session
- Deployment Strategies
- Integrating with Hadoop, Elastic Search, SOLR
- Ops War Stories
- Custom Tools and Monitoring
- [Capacity Planning]
- Evangelizing to DBAs

A MongoDB Masters Book

The MongoDB Masters are working together to write a book!

Focus and Audience

- Book should focus on MongoDB Pitfalls
- Make a "Bitter Mongo" like the "Bitter Java" book
  - Couching it right to ensure it doesn't prematurely prepare for problems is difficult
    - i.e. "This will bite you"
- Audience: MongoDB for the Accidental DBA
- 50 Tips and Tricks for MongoDB Developers
  - Kristina's book is really good
  - Good model for the MongoDB Masters Book

Content

- Support Tree for MongoDB Schemas
- Patterns that would be valuable
- Goldilocks versions i.e. Large, happy medium, small. What is just right.
- Schema Design Cookbook
  - (Blogging, logging and Cataloging)

Structure
• Let's get started
• Let's Avoid
• Let's Dig Ourselves Out
  • Blog + Comment
  • Simple models that people understand
  • Logging
  • Product Catalogues
  • Geospatial (geolocation)
  • Things you wouldn't think of
  • Quirky Use Cases
  • Choosing a Shard Key
  • Data Migration, Schema Migration
  • Managing Object Constellations for keeping quick queries

• Do the same piece in all different languages or frameworks?
  Node+express
  Python+Flask
  Skeletons to get started

Type and contributing

• AskIDoc as the type
  • PanDoc to convert formats.
  • Emacs
  • MOU for Mac.
  • Github pages to gather content

Quirky Ideas:

• Choose Your Own Adventure comic book?
  • Randall Schwartz

Custom Tools and Monitoring

Custom Tools & Monitoring
============================

Scope of discussion: Monitoring & Custom tools

Items most often monitored
~~~~~~~~~~~~~~~~~~~~~~~~~~

These items are the best indicators of a problem with MongoDB

• Replication lag
• page faults
• lock percentage
• IO usage

Additional Helpful Monitoring
~~~~~~~~~~~~~~~~~~~~~~~~~~~~

• Watch for long running queries
• Network Flakyness / DNS monitoring
• Chunk Imbalances
• Checking that queries are distributed evenly across shards

log scraping
~~~~~~~~~~~~

• looking or indications of fragmentation, (empty extents)
• Bursts of NotMaster

Long Term Strategies
---------------------

ODM Level Monitoring
~~~~~~~~~~~~~~~~~~~~

• looking for unsafe operations. Queries that do use an index
• Making ODM instrumented
• Query execution history
Profile queries as part Integration Testing that profiles queries

- Write queries predefined as application objects

Possible mailing list of hard to diagnose problems

- The type of problems which don't necessarily manifest themselves in the traditional indicators.

**Deployment Strategies**

**Deployment**

- **Hardware**
  - 12 x boxes, each with 512G RAM, SSD's, 4 x mongod each
  - Moving to 128G, 1 x mongod to avoid failures
  - Amazon 68G machines

- **OS**
  - Linux
    - 3 x people
  - Solaris
    - 0 x people

- **SSL**
  - commercial only
  - people using hacks; openvpn

- **repos**
  - ubuntu packages massively out of date
  - official packages always point to the latest version; how to pin to 2.x
  - missing init scripts / upstart scripts

- **Mongos**
  - most people 1 per application server
  - no init / upstart for mongos!

- **CFG**
  - on tiny boxes
  - spinning disks

- **Fabric**
  - niche

- **Puppet x 2**
  - not good for chaining stuff
  - configuration for different node types

- useful to enforce defaults + install

- **DNS configuration scripts**
  - Replacing nodes
  - if no-DNS, add instance, sync and remove old node

- **rs.addNode**
  - copy config from other node if first startup?

**Backups**

- EBS snapshots
- LVM snapshots
- Mongodump
- SAN attached

- Testing of backups
  - Not common
  - Not understood

**Evangelizing to DBAs**

Pushback from DBAs

Fanboi's and the haters:
• MongoDB is a hipster OS
• feel their pain
• Not wanting to give up control of schema design
• The converts are the most powerful evangelists
• Proactive monitoring

Marketing and messaging:
• call the talk: why not to use MongoDB (trick people into coming)
• safe zone for DBAs
• Saturday events for the Operations guy
• Chained to your desk online conferences for the overworked operations guys.

Culture issue:
• Fear of new technologies
• median age difference between NoSQL and RDBMS people
• core values: we will do it in code versus they do it in the DB

Ways to fixing it:
• explain the tradeoffs
• explain that there are distinct versions and formal releases

Good things:
• commercial support
• free community support
• knowledgebase
• its transparent open source
• Accept that training becomes consultation

Concrete action items:
• A #mongodbhelp blog post – DONE!
• More operations talks and docs
• SAS70 compliance
• Identifying a roadmap for tickets that would make DBAs happier
• Improving Instrumentation (e.g. performance counters)

Integrating with Hadoop, Elastic Search, SOLR
• 10gen has unofficially provided some connectors: Hadoop, Storm, Spark, Elastic Search, SOLR, Sphinx
• For search integration, seems like the common approach is to tail the oplog and send that to the service.

From Flavio:
• One approach was to start hacking on MongoDB's index API, which produced redundant indexing and inefficiency
• Two approach was to split the data at the application level
• Three was Elastic Search River
• One issue is based on timing - maybe tailing the oplog is not the right place to be triggering your index updates to the external application. If you do that work in your application, you can control the timing.
• An interesting use is Hive - non-developers will run hive queries as a sort of BI system. They also have daily mapreduce jobs that power the recommendation engine.
• There was a little integration with Pentaho, using the aggregation framework. Complaints with the moped driver and aggregation.
• Discussing 10gen-labs / mongo-connector as a framework for integration with external systems via tailing oplogs. Has examples for SOLR.
• We need an online community platform, as 10gen is doing great at in-person networking but there's little online.

Notes from 2012 MongoDB Masters Summit

Notes from 2012 MongoDB Masters Summit
• A MongoDB Masters Book
• ODM Breakout Session
• Schema Design Session
ODM Breakout Session

- Lots of ODMs in the ecosystem
- General consensus: Mongoose is leading the way.
- Balance: the right balance of features and what should be handled by the drivers.
- Mapping and validation will never be handled by the drivers, should be the job of the ODMs.
- It became clear that future ODMs should be split into as many components / modules as possible to allow people to choose how much they want from their ODM.

Ops War Stories

- sync from master is bad, lots of folks playing with iptables to block access to primaries for sync()
- mongod crashes fast when there are problems goes into the ground quickly. Query killer is key.
- be sure not to wait to long to shard, causes massive headaches. Can't get balancer to run when already out of capacity. Both space and OPS causes this problem.
- pre splitting is key.
- better mns docs, where is the spot where space utilization is shown over time?
- java thread growth, general sprawl over time. no good way to identify and kill session with open socket but dead in mongodb.
- People haven't really used client side timeouts, see previous bullet.
- array ops trigger crazy bugs in replication
- lots of frag problems, hopefully power of 2 allocation fixes
- need good way to measure fragmentation
- tailable cursor on oplog works ok on low latency connections, but not on wan
- load induced elections, load can cause primary to stop saying hello, and on top of high load an election happens.
- can't realistically perform bulk updates, no throttling mechanism built in folks build it into the app or don't do them. Floods oplog/replication.
- cluster wide backups/consistency is non-existent.
- if index key size is exceeded it fails quietly. really bad.
- if you kill any replication process it can leave holes in replication, really bad.
- no simple recovery tool for roll forward. Folks mentioned new oplog tool, but not really geared towards recovery.

Schema Design Session

- The session started with group concerns regarding the locking of deeply embedded documents and premature optimisation. Most people started out by embedding everything, but were quickly to realise that data without bounds (such as blog comments) should probably be broken out into separate collections (depending on use case).
- However, splitting things leads us a lack of atomicity.
- Lots of solutions and home-brewed 2 phase commits, logs and nonces were discussed - and doing things this way (rather than Hybrid applications, which are also 2 phase) makes more sense, as it can then be switched on and off depending on the use case allowing us to get the best of both worlds.
- Cool tips were also brought up regarding the use of collection names as ways to better perform mass deletion.

Technical Support

- Free Support Forum - http://groups.google.com/group/mongodb-user
- IRC Chat and Support - irc://irc.freenode.net/#mongodb
- Commercial Support

MongoDB Commercial Services Providers

10gen

10gen is the initiator, contributor and continual sponsor of the MongoDB project. 10gen offers
subscriptions that include production support, commercial licensing, and MongoDB Monitoring Service. In addition, 10gen offers advisory consulting and training.

Ready to learn more about 10gen? Fill out our contact form, and a 10gen representative will get in touch to learn about how 10gen services can help your organization.

Need support right away? If you are having a production issue and need support, please contact us, call us at (866) 237-8815, or visit the community Technical Support page.

Want to be listed here? If you provide consultative or support services for MongoDB and wish to be listed here, just let us know.

Hosting and Cloud

See the MongoDB Hosting Center.

Official 10gen Partners

10gen provides training to its systems integrator partners. To learn more about the partner program and what 10gen provides, or for information about joining the program, visit 10gen.com.

Job Board

Redirecting...

Gotchas

Note: This page was inspired by a blog post by rsmitth. Thanks. This page is intended to be a bit of a living document over time. At the time of its creation it is still a bit of a draft...

Always use 64 bit builds for production.

(MongoDB uses memory mapped files.) See the 32 bit doc page for more information.

32 bit builds exist to support use on development machines and also for other miscellaneous things such as replica set arbiters.

**BSON document size limit**

There is a limit – at the time of this writing 16MB per document. If you have large objects, use GridFS instead.

**Set an appropriate WriteConcern for your write operations**

MongoDB requires an explicit request for acknowledgement of the results of a write. This is the getLastError command. If you don't call it at all, that is likely bad – unless you are doing so with intent. The intent is to provide a way to do batch operations without continuous client/server turnarounds on every write of a batch of say, a million. The drivers support automatically calling this if you indicate a "write concern" for your connection to the database.

For example, if you try to insert a document above the BSON size limit indicated in the above section, getLastError/writeConcern would return an error – if you ask for those.

While this can be very useful when used appropriately, it is acknowledged this can be confusing at first as this is an untraditional pattern.
See also the getLastError/WriteConcern parameters – particularly ‘j’ and ‘w’ parameters.

**Schemaless does not mean you have no Schema**

(Headline here is quoting rsmith, thanks.)

MongoDB is referred to as "schemaless" as fields and the types of the values in fields are dynamic and flexible, even in a single collection. This makes iterative development and polymorphism much easier.

However, one does do schema design for applications using MongoDB. This can be very important. For fields there is an implicit schema: it is not unusual for collection’s to have highly homogenous document structures within them. Further, other aspects of the schema are:

- the exact set of collections to be used
- the indexes to be used, which are created explicitly except for the _id index
- shard key declarations, which are explicit and quite important as it is hard to change shard keys later

One very simple rule-of-thumb is to not verbatim import data from a relational database unmodified: you will generally want to "roll up" certain data into richer documents that use some embedding of nested documents and arrays (and/or arrays of subdocuments).

**Updates by default affect only one document**

Perhaps this should not have been the default. If you wish to modify many documents, set the multi update parameter to true. The mongo shell syntax is:

```
> db.my_collection_name.update(my_query, my_update_expression, bool_upsert, bool_multi)
```

Set bool_multi to true when updating many documents. Otherwise only the first matched will update!

**MongoDB strings are case sensitive**

So searching for "joe" will not find "Joe".

Consider:

- storing data in a normalized case format, or
- using regular expressions ending with /i
- and/or using $toLower or $toUpper in the aggregation framework

**Type sensitive fields**

MongoDB data – which is JSON-style, specifically, BSON format – has several data types. Thus if you have

```json
{ x : "123" }
```

the query

```
db.mycollection.find( { x : 123 } )
```

will not return that document as a result as the number 123 does not equal the string "123".

**Locking**

Older versions of MongoDB used a "global lock"; use MongoDB v2.2+ for better results. More info.

**Packages**

Be sure you have the latest stable release if you are using a package manager. You can see what is current on the Downloads page, even if you then choose to install via a package manager.

**Don’t use an even number of Replica Set members**

Replica sets perform consensus elections. Use either an odd number of members (e.g., three) or else use an arbiter to get up to an odd number
Don’t disable journaling

More info

Watch for lagging replica set members.

This is important as MongoDB replica sets support automatic failover. Thus you want your secondaries to be up-to-date. You have a few options here:

1. Monitoring and alerts for any lagging can be done via various means. MMS shows a graph of replica set lag
2. Using getLastError with w:'majority', you will get a timeout or no return if a majority of the set is lagging. This is thus another way to guard against lag and get some reporting back of its occurrence.
3. Or, if you want to fail over manually, you can set your secondaries to priority:0 in their configuration. Then manual action would be required for a failover. This is practical for a small cluster; for a large cluster you will want automation.

More info

More

• Pick your shard keys carefully! They cannot be changed except manually by making a new collection.
• You cannot shard an existing collection over 256G. This will eventually be removed but is a limit in the system today. You could as a workaround create a new sharded collection and copy over the data via some script – albeit that will likely take a while at this size.
• Unique indexes are not enforced across shards except for the shard key itself.
• Consider pre-splitting a sharded collection before a massive bulk import. Usually this isn’t necessary but on a bulk import of size it is helpful.
• Use security/auth mode if you need it. It is not on by default; rather a trusted environment is assumed.
• You do not have fully generalized transactions. Create rich documents and read the preceeding link and consider the use case – often there is a good fit.
• Disable NUMA - we find that works better. This will be printed as an informational warning at mongod startup on a NUMA box usually.
• Avoid excessive prefetch/readahead on the filesystem. Check your prefetch settings. Note on linux the parameter is in sectors, not bytes. 32KBytes (a setting of 64 sectors) is pretty reasonable.
• Check “limits” settings.
• Use SSD if available and economic. Spinning disks can work well but SSDs and MongoDB are a nice combo. See also: Production Notes for more info.
• Don’t go too crazy with pool sizes on clients. If you have 100 client machines and each has a pool size of 1000 connections, that would be a worst case of 100,000 connections to mongodb – which would be too much if to a single mongod or mongos (if to a cluster with many mongos, might be ok). So do the math and try to maintain a reasonable #. One thousand is fine, 100K, too much, 10K is ok.

Philosophy

Design Philosophy

• New database technologies are needed to facilitate horizontal scaling of the data layer, easier development, and the ability to store order(s) of magnitude more data than was used in the past.
• A non-relational approach is the best path to database solutions which scale horizontally to many machines.
• It is unacceptable if these new technologies make writing applications harder. Writing code should be faster, easier, and more agile.
• The document data model (JSON/BSON) is easy to code to, easy to manage(schemaless), and yields excellent performance by grouping relevant data together internally.
• It is important to keep deep functionality to keep programming fast and simple. While some things must be left out, keep as much as possible – for example secondaries indexes, unique key constraints, atomic operations, multi-document updates.
• Database technology should run anywhere, being available both for running on your own servers or VMs, and also as a cloud pay-for-what-you-use service.

Focus
MongoDB focuses on four main things: flexibility, power, speed, and ease of use. To that end, it sometimes sacrifices things like fine grained control and tuning, overly powerful functionality like MVCC that require a lot of complicated code and logic in the application layer, and certain ACID features like multi-document transactions.

**Flexibility**

MongoDB stores data in JSON documents (which we serialize to BSON). JSON provides us a rich data model that seamlessly maps to native programming language types, and since its schema-less, makes it much easier to evolve your data model than with a system with enforced schemas such as a RDBMS.

**Power**

MongoDB provides a lot of the features of a traditional RDBMS such as secondary indexes, dynamic queries, sorting, rich updates, upserts (update if document exists, insert if it doesn't), and easy aggregation. This gives you the breadth of functionality that you are used to from an RDBMS, with the flexibility and scaling capability that the non-relational model allows.

**Speed/Scaling**

By keeping related data together in documents, queries can be much faster than in a relational database where related data is separated into multiple tables and then needs to be joined later. MongoDB also makes it easy to scale out your database. Autosharding allows you to scale your cluster linearly by adding more machines. It is possible to increase capacity without any downtime, which is very important on the web when load can increase suddenly and bringing down the website for extended maintenance can cost your business large amounts of revenue.

**Ease of use**

MongoDB works hard to be very easy to install, configure, maintain, and use. To this end, MongoDB provides few configuration options, and instead tries to automatically do the "right thing" whenever possible. This means that MongoDB works right out of the box, and you can dive right into developing your application, instead of spending a lot of time fine-tuning obscure database configurations.

- Introduction

**Use Cases**

- Why do people use MongoDB?
- When should you consider using MongoDB?
- When should you use something else?
- If you had to pick one thing you wouldn't use it for, what's the first thing that comes to mind?
- Do big companies use MongoDB?
- Should I think of it as a system-of-record or as a caching tier?
- How many databases should my organization standardize on? Is one-size-fits-all over?
- Common Use Cases: Articles and Videos

The goal of MongoDB is to be a fairly general purpose tool that can be used for a variety of applications. Common uses include online/operational tasks and applications, as well as select business intelligence / analytics use cases.

The Production Deployments page provides hundreds of examples of real world use cases; see also the use case docs in the MongoDB Manual.
Why do people use MongoDB?

Two reasons: easy scale-out, and coding velocity ("agility").

The original catalyst for the NoSQL space is the growth of "big data" and the need for scalable databases to store that data. However, a secondary but often equally important factor in MongoDB adoption is increased software development "agility."

MongoDB developers report big productivity gains writing their apps, and often use Mongo regardless of whether scaling out is required. While there are MongoDB systems that exceed one million operations per second, MongoDB is also used for many apps that easily run on a single server.

MongoDB makes app development faster because it

1. eliminates object-relational-mapping work and the so-called "impedance mismatch". (Mongo uses JSON, which maps well to object-style data.)
2. allows dynamic schemas ("schemaless" operation), which is synergistic with agile software development methodologies, which themselves hugely speed project completion.
3. makes it much, much easier for the developer to store and manipulate complex data and polymorphic data.
4. reduces the amount of work required to scale out the application and increase system speed.

When should you consider using MongoDB?

The following attributes are good indicators you should consider MongoDB for your application:

- You find yourself coding around database performance issues – for example adding lots of caching.
- You are storing data in flat files.
- You are batch processing yet you need real-time.
- You are doing agile development, for example, Scrum. (MongoDB’s flexible schema enables iterative development.)
- Your data is complex to model in a relational db. For example a complex derivative security at an investment bank might be hard to store in a traditional relational format. Electronic health records is another example. If you were considering using an XML store, that’s a strong sign to consider MongoDB and its use of JSON/BSON.
- Your project is very late, and it is database intensive.
- You have been forced to use expensive SANs, proprietary servers, or proprietary networks for your existing database solution.
- You are deploying to a public or private cloud.
- Your application has simple requirements for transactions. MongoDB models data as documents, and single document updates are atomic and durable in MongoDB, unlike many other NoSQL products. This level of transactional functionality is sufficient for many applications. For example many users have built e-commerce systems using MongoDB.
- You have a workload that entails high volume ‘matching’ of records such as trade clearing, transaction reconciliation, fraud detection or system/software security applications.
- Several types of analytical workloads where one or more of the following are true:
  - the analytics are real-time
  - the data is very complicated to model in a relational schema
  - the data volume is huge
  - the source data is already in a mongo database
  - reporting can be addressed by the declarative aggregation functionality available in the aggregation framework (vv2.2+), or where more elaborate needs can be addressed by MongoDB’s MapReduce functionality
  - popular BI tools such as Jaspersoft and Pentaho can be used as these vendors have built integrations to MongoDB for reporting and visualization. Over time we expect other vendors to add support for MongoDB.
When should you use something else?

The following attributes are good indicators MongoDB may *not* be right for your application:

- **Applications that require SQL.** MongoDB supports ad hoc queries and has its own query language, but does not support SQL. This is likely a show stopper for many legacy apps until they are due for a refresh.
- **Applications with a heavy emphasis on complex transactions.** These systems typically require updates to multiple documents within a single transaction, XA transactions, multi-statement transactions, or other complex transactional operations, which MongoDB doesn't support.
- **Traditional Data Warehousing.** Traditional relational data warehouses are well suited for certain business intelligence problems and include complex or legacy SQL-based analytical workloads, or they require SQL for specific BI or reporting tools.

If you had to pick one thing you wouldn’t use it for, what’s the first thing that comes to mind?

A double-entry bookkeeping accounting system is probably the perfect anti-example.

- The intrinsically tabular application data maps well to relational data models
- The application requires very complex transactions at times
- The application requires a good amount of reporting. Relational and SQL are quite good at reporting
- The volume of data is probably relatively small

However, MongoDB is a good fit for reconciling data between two bookkeeping systems because 1) it speeds application development, 2) it stores and can query on data in different schemas, 3) it can rapidly execute the queries necessary for reconciliation, and 4) because this application does not require complex transactions.

Do big companies use MongoDB?

Yes. Quite a bit actually, from most industries including for example financial services, and including some companies with over $100B in annual revenues.

Should I think of it as a system-of-record or as a caching tier?

Both can be good use cases. Many, many systems are deployed by users where MongoDB is the system of record. But in addition, it can be a very good caching tier, it is fast, and in addition has good properties on a server or cluster restart as there is data persisted at the cache server.

How may databases should my organization standardize on? Is one-size-fits-all over?

Historically there is already some diversity: most large enterprises use an RDBMS for OLTP (e.g., Oracle), a data warehouse technology (e.g., Netezza), and some niche tools for special problems (e.g. a time series db).

Today we are seeing organizations add one more db tool to their toolbox: a NoSQL database.

We are also seeing some organizations (for example, one very large UK media company) adopt a *Mongo First* policy. That is to say, MongoDB is their *default* for building new applications. They use other tools, but by default, MongoDB. This is a good example that MongoDB is fairly general purpose. Note the word "application": they might at times use other things for pure reporting. Other companies are beginning to do this too; obviously these organizations have already done a few projects with MongoDB and are quite comfortable with it at this point.

Oh, and if you are a startup, just use MongoDB. :-)
provided which are necessary functions for large web sites' real-time data stores.

Business Intelligence

- Pentaho
- Jaspersoft
- Precog

Pentaho

Pentaho develops Enterprise and Community tools for business analytics and data integration. Pentaho's products integrate well with MongoDB, bringing Pentaho's visual interfaces for high-performance data ingestion, extraction and manipulation, data discovery, visualization, and predictive analytics to MongoDB. Specifically, Pentaho's tools provide a complete business analytics suite, visual tools to explore data in MongoDB, quick insights and reporting from MongoDB data and integration into enterprise-level analytics solutions.

To get started,

- Visit the Pentaho for MongoDB resource center.
- Once you've got MongoDB setup and running, download and install either the Pentaho Business Analytics Enterprise Edition or the Pentaho Kettle Community Edition.
- Next, review the Pentaho Big Data toolset and then learn about how to integrate MongoDB and Pentaho's tools.

Jaspersoft

Jaspersoft develops business intelligence tools and integration tools for data from several sources. Jaspersoft's intelligent connector integrates MongoDB with the full Jaspersoft BI Suite, providing flexible and affordable reporting, ad hoc analysis, and dashboarding of MongoDB data. As a result, both business and technical users can visualize and analyze MongoDB data more rapidly for competitive advantage. JasperReports Server supports native connections to MongoDB, both on-premises and in the cloud.

- First, install and setup MongoDB
- Next you can download and install JasperReports Server (Enterprise or Community) to create a centralized reporting infrastructure.
- To design reports download the iReport Report Designer.
- To get started, visit Simple Reporting on MongoDB for steps on using iReport to design reports with data from MongoDB.

Precog

Precog is a data science platform designed for developers and data scientists to build sophisticated big data capabilities into their applications. The Precog platform offers an end-to-end solution for programmatic big data analysis: from capture and storage, to cleaning and enrichment, to deep analysis designed to power intelligent, insightful features inside applications.

Precog has released a MongoDB implementation of the Precog platform, which bundles all of the Precog technology into a free package that anyone can download. Precog for MongoDB empowers companies to quickly and easily build advanced big data analytics features into their applications on top of their existing MongoDB database. With Precog, you can now analyze all the data in your MongoDB database, without forcing you to export data into another tool or write any custom code. To get started:

- Visit the Precog for MongoDB webpage.
- Complete the short form to download the zipped file (includes JAR, scripts and config file).
- Visit our Developer Center for the installation and configuration instructions. If you run into any trouble, please email the Precog team at support@precog.com.

Hadoop Quick Start

- Prerequisites
  - Hadoop
  - MongoDB
  - Miscellaneous
- Building MongoDB Adapter
- Examples
  - Load Sample Data
  - Treasury Yield
  - UFO Sightings

MongoDB and Hadoop are a powerful combination and can be used together to deliver complex analytics and data processing for data stored in MongoDB. The following guide shows how you can start working with the MongoDB-Hadoop adapter. Once you become familiar with the adapter, you can use it to pull your MongoDB data into Hadoop Map-Reduce jobs, process the data and return results back to a MongoDB collection.

Prerequisites

Hadoop
In order to use the following guide, you should already have Hadoop up and running. This can range from a deployed cluster containing multiple nodes or a single node pseudo-distributed Hadoop installation running locally. As long as you are able to run any of the examples on your Hadoop installation, you should be all set. The following versions of Hadoop are currently supported:

- 0.20/0.20.x
- 1.0/1.0.x
- 0.21/0.21.x
- CDH3
- CDH4

### MongoDB

The latest version of MongoDB should be installed and running. In addition, the MongoDB commands should be in your PATH.

### Miscellaneous

In addition to Hadoop, you should also have git and JDK 1.6 installed.

### Building MongoDB Adapter

The MongoDB-Hadoop adapter source is available on github. First, clone the repository and get the release-1.0 branch:

```
$ git clone https://github.com/mongodb/mongo-hadoop.git
$ git checkout release-1.0
```

Now, edit build.sbt and update the build target in hadoopRelease in ThisBuild. In this example, we're using the CDH3 Hadoop distribution from Cloudera so I'll set it as follows:

```
hadoopRelease in ThisBuild := "cdh3"
```

To build the adapter, use the self-bootstrapping version of sbt that ships with the MongoDB-Hadoop adapter:

```
$ ./sbt package
```

Once the adapter is built, you will need to copy it and the latest stable version of the MongoDB Java driver to your $HADOOP_HOME/lib directory. For example, if you have Hadoop installed in /usr/lib/hadoop:

```
$ wget --no-check-certificate https://github.com/downloads/mongodb/mongo-java-driver/mongo-2.7.3.jar
$ cp mongo-2.7.3.jar /usr/lib/hadoop/lib/
$ cp core/target/mongo-hadoop-core_cdh3u3-1.0.0.jar /usr/lib/hadoop/lib/
```

### Examples

#### Load Sample Data

The MongoDB-Hadoop adapter ships with a few examples of how to use the adapter in your own setup. In this guide, we'll focus on the UFO Sightings and Treasury Yield examples. To get started, first load the sample data for these examples:

```
$ ./sbt load-sample-data
```

To confirm that the sample data was loaded, start the mongo client and look for the mongo_hadoop database and be sure that it contains the ufo_sightings.in and yield_historical.in collections:
$ mongo
MongoDB shell version: 2.0.5
connecting to: test
> show dbs
mongo_hadoop 0.453125GB
> use mongo_hadoop
switched to db mongo_hadoop
> show collections
system.indexes
ufo_sightings.in
yield_historical.in

Treasury Yield

To build the Treasury Yield example, we'll need to first edit one of the configuration files uses by the example code and set the MongoDB location for the input (mongo.input.uri) and output (mongo.output.uri) collections (in this example, Hadoop is running on a single node alongside MongoDB):

$ emacs examples/treasury_yield/src/main/resources/mongo-treasury_yield.xml
...
<property>
  <!-- If you are reading from mongo, the URI -->
  <name>mongo.input.uri</name>
  <value>mongodb://127.0.0.1/mongo_hadoop.yield_historical.in</value>
</property>
<property>
  <!-- If you are writing to mongo, the URI -->
  <name>mongo.output.uri</name>
  <value>mongodb://127.0.0.1/mongo_hadoop.yield_historical.out</value>
</property>
...

Next, edit the main class that we'll use for our MapReduce job (TreasuryYieldXMLConfig.java) and update the class definition as follows:

$ emacs examples/treasury_yield/src/main/java/com/mongodb/hadoop/examples/treasury/TreasuryYieldXMLConfig.java
...
public class TreasuryYieldXMLConfig extends MongoTool {
    static{
        // Load the XML config defined in hadoop-local.xml
        Configuration.addDefaultResource( "hadoop-local.xml" );
        Configuration.addDefaultResource( "mongo-defaults.xml" );
        Configuration.addDefaultResource( "mongo-treasury_yield.xml" );
    }

    public static void main( final String[] pArgs ) throws Exception{
        System.exit( ToolRunner.run( new TreasuryYieldXMLConfig(), pArgs ) );
    }
}
...

Now let's build the Treasury Yield example:

$ ./sbt treasury-example/package

Once the example is done building we can submit our MapReduce job:
This job should only take a few moments as it's a relatively small amount of data. Now check the output collection data in MongoDB to confirm that the MapReduce job was successful:

```bash
$ mongo
MongoDB shell version: 2.0.5
connecting to: test
> use mongo_hadoop
switched to db mongo_hadoop
> db.yield_historical.out.find()
{ "_id": 1990, "value": 8.552400000000002 }
{ "_id": 1991, "value": 7.8623600000000025 }
{ "_id": 1992, "value": 7.008844621513946 }
{ "_id": 1993, "value": 5.866279999999999 }
{ "_id": 1994, "value": 7.085180722891565 }
{ "_id": 1995, "value": 6.573920000000002 }
{ "_id": 1996, "value": 6.443531746031742 }
{ "_id": 1997, "value": 6.353959999999992 }
{ "_id": 1998, "value": 5.262799999999994 }
{ "_id": 1999, "value": 5.64613548387097 }
{ "_id": 2000, "value": 6.03027884462145 }
{ "_id": 2001, "value": 5.0206854837097 }
{ "_id": 2002, "value": 4.61308 }
{ "_id": 2003, "value": 4.013879999999999 }
{ "_id": 2004, "value": 4.271320000000004 }
{ "_id": 2005, "value": 4.288880000000001 }
{ "_id": 2006, "value": 4.7949999999999955 }
{ "_id": 2007, "value": 4.63466135481674 }
{ "_id": 2008, "value": 3.6642629482071714 }
{ "_id": 2009, "value": 3.2641200000000037 }
has more
```

**UFO Sightings**

This will follow much of the same process as with the Treasury Yield example with one extra step; we'll need to add an entry into the build file to compile this example. First, open the file for editing:

```bash
$ emacs project/MongoHadoopBuild.scala
```

Next, add the following lines starting at line 72 in the build file:

```scala
...  
    lazy val ufoExample = Project( id = "ufo-sightings",
        base = file("examples/ufo_sightings"),
        settings = exampleSettings ) dependsOn ( core )
...  
```

Now edit the UFO Sightings config file and update the `mongo.input.uri` and `mongo.output.uri` properties:
Next edit the main class for the MapReduce job in `UfoSightingsXMLConfig.java` to use the configuration file:

```java
public class UfoSightingsXMLConfig extends MongoTool {
    static {
        // Load the XML config defined in hadoop-local.xml
        // Configuration.addDefaultResource( "hadoop-local.xml" );
        Configuration.addDefaultResource( "mongo-defaults.xml" );
        Configuration.addDefaultResource( "mongo-ufo_sightings.xml" );
    }

    public static void main( final String[] pArgs ) throws Exception{
        System.exit( ToolRunner.run( new UfoSightingsXMLConfig(), pArgs ) );
    }
}
```

Now build the UFO Sightings example:

```
$ ./sbt ufo-sightings/package
```

Once the example is built, execute the MapReduce job:

```
$ hadoop jar examples/ufo_sightings/target/ufo-sightings_cdh3u3-1.0.0.jar com.mongodb.hadoop.examples.UfoSightingsXMLConfig
```

This MapReduce job will take just a bit longer than the Treasury Yield example. Once it's complete, check the output collection in MongoDB to see that the job was successful:

```
$ mongo
MongoDB shell version: 2.0.5
connecting to: test
> use mongo_hadoop
switched to db mongo_hadoop
> db.ufo_sightings.out.find().count()
21850
```

Hadoop Scenarios
The following are some example deployments with MongoDB and Hadoop. The goal is to provide a high-level description of how MongoDB and Hadoop can fit together in a typical Big Data stack. In each of the following examples MongoDB is used as the “operational” real-time data store and Hadoop is used for offline batch data processing and analysis.

**Batch Aggregation**

In several scenarios the built-in aggregation functionality provided by MongoDB is sufficient for analyzing your data. However in certain cases, significantly more complex data aggregation may be necessary. This is where Hadoop can provide a powerful framework for complex analytics.

In this scenario data is pulled from MongoDB and processed within Hadoop via one or more Map-Reduce jobs. Data may also be brought in from additional sources within these Map-Reduce jobs to develop a multi-datasource solution. Output from these Map-Reduce jobs can then be written back to MongoDB for later querying and ad-hoc analysis. Applications built on top of MongoDB can now use the information from the batch analytics to present to the end user or to drive other downstream features.

**Data Warehouse**

In a typical production scenario, your application’s data may live in multiple datastores, each with their own query language and functionality. To reduce complexity in these scenarios, Hadoop can be used as a data warehouse and act as a centralized repository for data from the various sources.

In this situation, you could have periodic Map-Reduce jobs that load data from MongoDB into Hadoop. This could be in the form of “daily” or “weekly” data loads pulled from MongoDB via Map-Reduce. Once the data from MongoDB is available from within Hadoop, and data from other sources are also available, the larger dataset data can be queried against. Data analysts now have the option of using either Map-Reduce or Pig to create jobs that query the larger datasets that incorporate data from MongoDB.

**ETL Data**

MongoDB may be the operational datastore for your application but there may also be other datastores that are holding your organization’s data. In this scenario it is useful to be able to move data from one datastore to another, either from your application’s data to another database or vice
versa. Moving the data is much more complex than simply piping it from one mechanism to another, which is where Hadoop can be used.

In this scenario, Map-Reduce jobs are used to extract, transform and load data from one store to another. Hadoop can act as a complex ETL mechanism to migrate data in various forms via one or more Map-Reduce jobs that pull the data from one store, apply multiple transformations (applying new data layouts or other aggregation) and loading the data to another store. This approach can be used to move data from or to MongoDB, depending on the desired result.

How MongoDB is Used in Media and Publishing

We see growing usage of MongoDB in both traditional and new media organizations. In these areas, the challenges for application developers include effectively managing rich content (including user-generated content) at scale, deriving insight into how content is consumed and shared in real-time, weaving personalization and social features into their applications and delivering content to a wide variety of browsers and devices.

From a data storage perspective, there is a need for databases that make it easy to rapidly develop and deploy interactive, content-rich web and mobile application, while cost-effectively meeting performance and scale requirements. Specifically, MongoDB is good fit for application across the media and publishing world for the following reasons:

- The document model is natural fit content-rich data
- Schema-free JSON-like data structures make it easy to import, store, query, and deliver structured and semi-structured content
- High-performance and horizontal scalability for both read and write intensive applications

MongoDB for Content management

MongoDB’s document model makes it easy to model content and associated metadata in flexible ways. While the relational model encourages dividing up related data into multiple tables, the document model (with its support for data structures such as arrays and embedded documents)
encourages grouping related pieces of data within a single document. This leads to a data representation that is both efficient and closely
matches objects in your application.

As an example, the following document represents how a blog post (including its tags and comments) can be modeled with MongoDB:

```
{
    _id: ...
    author: "Nosh"
    title: "Why MongoDB is good for CMS"
    date:11/29/2010
    body: "MongoDB’s document model makes it easy to model...."
    tags: ["media", "CMS", "web", "use case"]
    comments: [{author:bob, date:1/1/2011, comment:"I agree"},{..}, {..}]
}
```

Modeling content elements with these patterns also simplifies queries. For example, we can retrieve all blog posts by the author 'nosh' which have
the tag mongodb with the query,

```
find({author:"nosh", tags:"mongodb")
```

Flexible document-based representation, efficient and simple queries and scalability makes MongoDB a well suited as a datastore for content
management systems. The Business Insider has built their content management system from the ground up using MongoDB and PHP, which
serves over 2 million visits/month. For sites based on Drupal, Drupal 7 now makes it easier to use MongoDB as a datastore. Examiner.com, ported their legacy CMS (based on ColdFusion and Microsoft SQLServer) to Drupal 7 and a hybrid of MySQL and MongoDB. You can read a
case study about the how the examiner.com (a top 100 website, and one of most trafficked Drupal deployments) made the transition.

MongoDB can also be used to augment existing content management systems with new functionality. One area that we see MongoDB used
increasingly is as a metadata store for rich media. MongoDB’s document model makes it simple to represent the attributes for an asset (e.g.
author, dates, categories, versions, etc) and a pointer to the asset (e.g. on a filesystem or on S3) as document and then efficiently search or query
the metadata for display. Additionally, because MongoDB is schema-free, new metadata attributes can be added without having to touch existing
records. IGN uses MongoDB as a the metadata store for all videos on IGN Videos and serves up millions of video views per month. Another
similar use case for MongoDB is in storing user-submitted content. The New York Times, uses MongoDB as the backend for ‘Stuffy’, their tool for
allowing users and editors to collaborate on features driven by user-submitted photos. A brief overview on the tool is here.

**How-to Guides**

Modeling content, comments, and tags with MongoDB (coming soon)
Modelling image and video metadata with MongoDB (coming soon)
Using MongoDB with Drupal 7 (coming soon)

Roadmap tip: Watch the full-text search ticket

**MongoDB for Real-time analytics**

The ability to track and change content based on up-to-minute statistics is becoming increasingly important. MongoDB’s fast write performance
and features such as upsert and the $inc operator, make it well suited for capturing real time analytics on how content is being consumed. This
blog post outlines some basic patterns you can use to capture real-time pageview statistics for your content.

A number of companies are using MongoDB, either internally to track their own content in real-time, or are building platforms based on MongoDB
to help other companies get real time statistics on their content: Chartbeat provides analytics for publishers, with live dashboards and APIs
showing how users are engaging with their content in real-time. BuzzFeed uses MongoDB to help understand how and when content will go viral,
while ShareThis uses MongoDB to power its API that gives publishers insight into how content is shared across the web and social media

**How-to guides**

Real-time analytics with MongoDB (coming soon)

**MongoDB for Social Graphs & Personalization**

While systems such as graph databases excel at complex graph traversal problems, MongoDB’s document structure is well suited for building
certain types of social and personalization features. Most often, this involves building user profile documents that include a list of friends, either
imported from external social networks or in site. For example,
In this case the friendIDs field is an array with a list of IDs corresponding to profiles of users that are my friends. This data can then be used to generate personalized feeds based on content that my friends have viewed or liked. IGN's social network, MY IGN, uses MongoDB to store profiles of users and generate personalized fields. Users have the ability to import their friends from facebook, ‘follow’ IGN authors, or follow specific game titles they are interested in. When they log in, they are presented with a personalized feed composed from this data.

**How-to guides:**

Storing user profiles with MongoDB (coming soon)
Importing social graphs into MongoDB (coming soon)
Generating personalized feeds with MongoDB (coming soon)

**MongoDB for Mobile/Tablet Apps**

Serving similar content across desktop browsers, mobile browsers, as well as mobile apps is driving developers to build standardized API layers that can be accessed by traditional web application servers, mobile client applications, as well as 3rd party applications. Typically these are RESTful APIs that serve JSON data. With MongoDB’s JSON-like data format, building these APIs on top of MongoDB is simplified as minimal code is necessary to translate MongoDB documents and query to JSON representation. Additionally, features such as in-built two-dimensional geospatial indexing allow developers to easily incorporate location-based functionality into their applications.

**MongoDB for Data-driven journalism**

One of the strengths of MongoDB is dealing with semi-structured data. Data sources such as those produced by governments and other organizations are often denormalized and distributed in formats like CSV files. MongoDB, with its schema-free JSON-like documents is an ideal store for processing and storing these sparse datasets.

The Chicago Tribune uses MongoDB in its Illinois School Report Cards application, which is generated from a nearly 9,000 column denormalized database dump produced annually by the State Board of Education. The application allows readers to search by school name, city, county, or district and to view demographic, economic, and performance data for both schools and districts.

**How-to guides:**

Importing and Exporting data from MongoDB (coming soon)
Reporting and Visualization with MongoDB (coming soon)

**Use Case - Session Objects**

MongoDB is a good tool for storing HTTP session objects.

One implementation model is to have a sessions collection, and store the session object’s _id value in a browser cookie.

With its update-in-place design and general optimization to make updates fast, the database is efficient at receiving an update to the session object on every single app server page view.

**Aging Out Old Sessions**

The best way to age out old sessions is to use the auto-LRU facility of capped collections. The one complication is that objects in capped collections may not grow beyond their initial allocation size. To handle this, we can “pre-pad” the objects to some maximum size on initial addition, and then on further updates we are fine if we do not go above the limit. The following mongo shell javascript example demonstrates padding.

(Note: a clean padding mechanism should be added to the db so the steps below are not necessary.)
> db.createCollection('sessions', { capped: true, size : 1000000 })
("ok" : 1)
> p = "";
> for x = 0; x < 100; x++ } p += 'x';
> s1 = { info: 'example', _padding : p }
("info" : "example" , "_padding" :
"xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx"
})
> db.sessions.save(s1)
> s1
("info" : "example" , "_padding" :
"xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx"
,"_id" : ObjectId("4aafb74a5761d14767233b0")
})
> // when updating later
> s1 = db.sessions.find( { _id : ObjectId("4aafb74a5761d14767233b0") } }
("_id" : ObjectId("4aafb74a5761d14767233b0") , "info" : "example" , "_padding" :
"xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx"
})
> delete s._padding;
true
> s.x = 3; // add a new field
3
> db.sessions.save(s);
> s
("_id" : ObjectId("4aafb5a25761d147677233af") , "info" : "example" , "x" : 3}
**HarmonyApp**

Harmony is a powerful web-based platform for creating and managing websites. It helps connect developers with content editors, for unprecedented flexibility and simplicity. For more information, view Steve Smith's presentation on Harmony at MongoSF (April 2010).

**Hummingbird**

Hummingbird is a real-time web traffic visualization tool developed by Gilt Groupe.

**Locomotive**

*Locomotive* is an open source CMS for Rails. It's flexible and integrates with Heroku and Amazon S3.

**Mogade**

Mogade offers a free and simple to use leaderboard and achievement services for mobile game developers.

**MongoLantern**

*MongoLantern* is an open source full text search server using MongoDB as index storage, which allows MongoLantern to migrate any changes very easily into account using MongoDB API. It's written originally written in PHP can be migrated to any desired language as required using it's future APIs.

**MongoPress**

A flexible CMS that uses MongoDB and PHP.

**Mongs**

A simple, web-based data browser for MongoDB.

**Mongeez**

Mongeez is an opensource solution allowing you to manage your mongo document changes in a manner that is easy to synchronize with your code changes. Check out mongeez.org.

**NewsBlur**

NewsBlur is an open source visual feed reader that powers http://newsblur.com. NewsBlur is built with Django, MongoDB, Postgres and RabbitMQ.

**Quantum GIS**

Plugin for Quantum GIS that lets you plot geographical data stored in MongoDB.

**Scribe**

Open source image transcription tool.

**Shapado**

Free and open source Q&A software, open source stackoverflow style app written in ruby, rails, mongomapper and mongodb.

**Strider**

Strider: Open Source Continuous Integration & Deployment Server.

**Thundergrid**

Thundergrid is a simple framework written in PHP that allows you to store large files in your Mongo database in seconds.

**Websko**

Websko is a content management system designed for individual Web developers and cooperative teams.

If you're interested in having someone present MongoDB at your conference or meetup, or if you would like to list your MongoDB event on this page, contact meetups at 10gen dot com. Want some MongoDB stickers to give out at your talk? Complete the Swag Request Form.

MongoDB Study Groups
10gen will be sponsoring a number of community-run MongoDB study groups around the globe to go along with MongoDB's Free Online Education initiative. Find a study group near you or find out how to start your own!

**Training**

MongoDB training from 10gen is the best way to get you and your team up to speed quickly. Our MongoDB Developer Training and MongoDB Administrator Training are comprehensive, two day courses.

Contact us at training@10gen.com if you would like to buy training credits for multiple students or classes, schedule an on-site training, or discuss a custom training option.

**MongoDB Study Groups**

In order to facilitate community through our education courses, 10gen will be sponsoring a number of MongoDB study groups around the globe so everyone from novices to experts can support one another as they learn. You can meet weekly, monthly or whenever you like to guide one another through the lessons and walk away better prepared to put MongoDB into production.
Interested in creating a MongoDB study group in your area? Send a note to our community team and we’ll help you get started. If you’re a user group member, consider organizing a MongoDB study group through your local MUG.

New York MongoDB Study Group
- Next Meeting November 26

Hamburg MongoDB Study Group

St Petersburg MongoDB Study Group
- Join the Russian MongoDB Mailing List to be notified of future Meetings

MongoDB Lima Study Group
- October 28 (First week)
- November 4 (Second week)
- November 11 (Third week)
- November 25
- December 9 (Sixth Week)

MongoDB User Groups (MUGs)

MongoDB User Groups (MUGs) are a great way for the community to learn from one another about MongoDB best practices, to network, and to have fun. Interested in starting a user group in your city? Submit a proposal and check out our guide to starting a MongoDB User Group to get started! Need some ideas? Check out our go-to-guide for running a MongoDB user group.

If you're interested in having someone present MongoDB at your conference or meetup, or if you would like to list your MongoDB event on this page, contact meghan at 10gen dot com.

Your Go-to Resource for Running a MongoDB User Group
Tips for Running a Successful User Group

Interested in Starting a User Group?

Organizing a user group is a fantastic way to meet and learn from other MongoDB fans in your local community. Interested in starting up a user group in your city? Submit a proposal!

Logistics

Use Meetup.com: This one may be obvious but important to emphasize. Not only does meetup have a lot of great tools for event organizers, but they do a really good job of making it easy for meetup members to find relevant groups. Make sure to tag your group and include a description with keywords so that your group appears in meetup searches!

Consistency is important: It's important to establish a routine early on. If you consistently meet on the second Tuesday of every month, your members will come to expect the meetup. The first few meetings of any user group will be small, but at every meetup, new members will join your group. So meeting at least on a monthly basis is very important. We have all the NY MUG meetups listed far in advance, even if we don't have a speaker lined up. This also makes your life easier when you are approaching speakers and hosts. It's much easier to ask a speaker "Can you present at the May 19 NY MUG?" than going back and forth coordinating dates. And hosts will appreciate having the events reserved far in advance.

Cross promote: Consider partnering with other technology meetups. This is a great way for communities to learn from one another and gain exposure to new technologies. It could be as simple as occasionally posting on other meetup lists. For example, when we had a presentation on Scalable Event Analytics with Ruby on Rails and MongoDB, I cross-posted the meetup on the NYC Ruby mailing list and we soon had a dozen new members in the group. I also typically list our events in Startup Digest, LinkedListNYC, Gary's Guide, Charlie O'Donnell's newsletter, Mashable, and more.

Working with Speakers

Create a Speaker Checklist (tip courtesy of Joe Devon)

- Get the full details about your speakers before putting it on the event page
  1. Speaker bio and small photo.
  2. Company "about us" and small logo.
  3. Title of Talk.
  4. Abstract of Talk.
  5. Social Media / Corp homepage / etc... links.
  6. Phone numbers (to coordinate the day of the event)

Once you Meet Up...

Get great speakers: Make a wish list of speakers, and then just start asking people! After organizing dozens of MongoDB events, I've been amazed at how willing people are to present. Most of the time, it's just a matter of asking. And if the person says no, ask them to refer someone else.

Get Clever About Getting Great Speakers: Are the speakers on your wish list 3,000 miles away from you? That's okay. We live in a wired world. Use Skype or WebX to bring your speakers to you. You can do screen shares to see demos, and provide your meetup members with a great learning experience.

Host Lightning Talks: Sometimes your user group members will not have the chance to pull together a full 30 minute presentation on a product or feature, but some of them may be interested in giving a 5-10 minute lightning talk on something they've designed, an issue they're having with MongoDB, or their dream project. Offer the opportunity when you send out the Meetup invite. If you don't get any submissions, don't worry. Deliver the first lightning talk at the event. Someone might step up to the plate.

Start a Study Group: Does your meetup have a lot of inexperienced MongoDB Users? Start a study group and learn together. Learning in a group is a great experience, and study groups are very common in different developer communities--particularly Ruby on Rails and Node.js

Host a Helpathon: The NYC On Rails Meetup is famous for innovating on the Hackathon to produce the Helpathon, a four hour session for helping one another get through programming hurdles.

Start a Book Club: If your group is at a loss for topics to discuss you could start a reading group. This is similar to a study group and can be a great way to create a more tightly knit User Group for the future.

Raffle off prizes: Prizes are an excellent way to get people to come to your meetup. An easy and free way to get great prizes is to join the O'Reilly User Group program. They will send you free books to give out at your group, as well as discounts on upcoming conferences.
Host a Coding Contest: Google is planning a coding competition for tickets to Google I/O, their largest developer contest. Why not do the same before your first user group? Present a small problem to your members and ask them to bring their files the day of to show off their solution. You can then have judges or the audience choose the winning solution(s).

Stay Engaged

Social media: Consider creating a twitter handle or hashtag for the group. Ask the presenter to tweet or blog about the event, and ask the key members of the group to do the same. Post the hashtag or twitter handle at the event so that members know to use it.

Continue the discussion after the meetup: You can easily record videos and take photos at sessions to share information after the meetup. Encourage the presenter to send a message the group with the slides to start a conversation among the entire meetup.

Send out Group Polls: Get a better understanding of what your user group wants to hear by sending out polls. If you use Meetup.com, you can try out the Polls feature. Otherwise, use SurveyMonkey.

Presentation tips for speaking at a MongoDB User Group

Presentation Tips for MongoDB User Groups

Presenting at a MongoDB User Group (MUG) is a great way to share your experiences working with MongoDB, drive adoption of your product and create a closer connection between your company’s services and MongoDB. If you’re new to public speaking, it’s a great place to get presentation experience or test out a talk for a future conference. Here are some tips for giving presentations at a user group.

Have a suggestion that’s not listed here? Email our community team with your ideas.

Content: What Should I Talk About At a User Group?

• Teach them something: MongoDB User Group members have different levels of experience with MongoDB but everyone has the same goal: they want to learn more. Offering your insights, tips and tricks often turns into a great presentation with a lot of discussion.
  • Many people in our user groups are new to MongoDB, while others are veterans and have years of experience under their belt but are interested in expanding their knowledge base. It’s sometimes a good idea to ask the user group organizer about the experience level of their members so you can cater your presentation their interests.

• Some great topics for a MongoDB User Group (with some examples)
  • MongoDB in the Cloud
    • Growing MongoDB on Amazon Web Services
    • MongoDB on AWS
  • Monitoring Your MongoDB Deployment
  • How I use MongoDB in Production
    • Krossover + MongoDB
    • Fiesta.cc + MongoDB
  • Inside Wordnik’s Architecture
  • MongoDB in a Specific Language Library
    • MongoDB and PHP
  • Getting Started with MongoDB and Scala
  • MongoDB and Big Data
    • SQL, NoSQL and Big data Architecture, by Venu Anuganti
    • MongoDB on the JVM

• Want to get your feet wet? Offer to give a 5-10 minute lightening talk or demo of a MongoDB tool to build up your presentation skills.

Slides

• Be precise in your slides - Most user group organizers make slides available online after the user group, so make sure they are correct and to the point.
• Be visual - a clever picture, easy to read chart, or even simple bullet points convey clear information.
• Use Big Font! Some meeting rooms are large and it is always hard to see from the back of the room
• Avoid including full text such as sentences and paragraphs in your slides. This makes it difficult for people to pay attention to your thoughts and expertise. You should be the center of the presentation, the slides should be there to guide you.
• Know your audience - The audience is very technical, and generally knowledgeable about MongoDB and related technologies. They are interested in hearing your insights and experience so they can become better MongoDB developers.
• Some great resources to help you build well-designed slides:
  • Duarte have great insight into presentation design and storytelling. Check out their blog for weekly tips and their Tools for Revolutionaries with free video guides to reworking your presentations.
Logistics

- Ask the organizer what time you should arrive (also be courteous and arrive on time)
- Make sure your computer or presentation will be compatible with the presentation setup available at the meetup group. Ask the organizer to make sure you have the correct connecting equipment. If you need a different adaptor for your laptop, please try to bring it with you.
- Send you presentations to the organizer so they can distribute it with the group. It's great to share this information.
- Internet connectivity: wifi can be tedious in some places. To avoid any painful situations with wifi, try to make any demos in your presentations available offline.
- Invite your friends! It's always fun to bring along friends, family and coworkers to a user group—but be sure to check with the organizer to ensure the meeting location has enough capacity.

MongoDB Archives and Articles

**v2.2**

The v2.2 release is now available. In addition to hundreds of smaller improvements, the release includes these major features:

- the new aggregation framework which makes reporting-type queries much easier;
- large improvements in mongod internal concurrency (no more global lock);
- tag-aware sharding / data center awareness features
- TTL collections

You can download v2.2 here.

- Full release notes here.

**Comparing Mongo DB and Couch DB**

We are getting a lot of questions "how are mongo db and couch different?" It's a good question: both are document-oriented databases with schemaless JSON-style object data storage. Both products have their place -- we are big believers that databases are specializing and "one size fits all" no longer applies.

We are not CouchDB gurus so please let us know in the forums if we have something wrong.

**MVCC**

One big difference is that CouchDB is MVCC based, and MongoDB is more of a traditional update-in-place store. MVCC is very good for certain classes of problems: problems which need intense versioning; problems with offline databases that resync later; problems where you want a large amount of master-master replication happening. Along with MVCC comes some work too: first, the database must be compacted periodically, if there are many updates. Second, when conflicts occur on transactions, they must be handled by the programmer manually (unless the db also does conventional locking -- although then master-master replication is likely lost).
MongoDB updates an object in-place when possible. Problems requiring high update rates of objects are a great fit; compaction is not necessary. MongoDB's replication works great but, without the MVCC model, it is more oriented towards master/slave and auto failover configurations than to complex master-master setups. With MongoDB you should see high write performance, especially for updates.

**Horizontal Scalability**

One fundamental difference is that a number of Couch users use replication as a way to scale. With Mongo, we tend to think of replication as a way to gain reliability/failover rather than scalability. MongoDB uses (auto) sharding as our path to scalability (sharding is GA as of 1.6). In this sense MongoDB is more like Google BigTable. (We hear that Couch might one day add partitioning too.)

**Query Expression**

Couch uses a clever index building scheme to generate indexes which support particular queries. There is an elegance to the approach, although one must predeclare these structures for each query one wants to execute. One can think of them as materialized views.

Mongo uses traditional dynamic queries. As with, say, MySQL, we can do queries where an index does not exist, or where an index is helpful but only partially so. Mongo includes a query optimizer which makes these determinations. We find this is very nice for inspecting the data administratively, and this method is also good when we don't want an index: such as insert-intensive collections. When an index corresponds perfectly to the query, the Couch and Mongo approaches are then conceptually similar. We find expressing queries as JSON-style objects in MongoDB to be quick and painless though.

Update Aug2011: Couch is adding a new query language "UNQL".

**Atomicity**

Both MongoDB and CouchDB support concurrent modifications of single documents. Both forego complex transactions involving large numbers of objects.

**Durability**

CouchDB is a "crash-only" design where the db can terminate at any time and remain consistent.

Previous versions of MongoDB used a storage engine that would require a repairDatabase() operation when starting up after a hard crash (similar to MySQL's MyISAM). Version 1.7.5 and higher offer durability via journaling; specify the --journal command line option

**Map Reduce**

Both CouchDB and MongoDB support map/reduce operations. For CouchDB map/reduce is inherent to the building of all views. With MongoDB, map/reduce is only for data processing jobs but not for traditional queries.

**Javascript**

Both CouchDB and MongoDB make use of Javascript. CouchDB uses Javascript extensively including in the building of views.

MongoDB supports the use of Javascript but more as an adjunct. In MongoDB, query expressions are typically expressed as JSON-style query objects; however one may also specify a javascript expression as part of the query. MongoDB also supports running arbitrary javascript functions server-side and uses javascript for map/reduce operations.

**REST**

Couch uses REST as its interface to the database. With its focus on performance, MongoDB relies on language-specific database drivers for access to the database over a custom binary protocol. Of course, one could add a REST interface atop an existing MongoDB driver at any time -- that would be a very nice community project. Some early stage REST implementations exist for MongoDB.

**Performance**

Philosophically, Mongo is very oriented toward performance, at the expense of features that would impede performance. We see MongoDB being useful for many problems where databases have not been used in the past because databases are too “heavy”. Features that give MongoDB good performance are:

- client driver per language: native socket protocol for client/server interface (not REST)
- use of memory mapped files for data storage
- collection-oriented storage (objects from the same collection are stored contiguously)
- update-in-place (not MVCC)
- written in C++

**Use Cases**

It may be helpful to look at some particular problems and consider how we could solve them.
if we were building Lotus Notes, we would use Couch as its programmer versioning reconciliation/MVCC model fits perfectly. Any problem where data is offline for hours then back online would fit this. In general, if we need several eventually consistent master-master replica databases, geographically distributed, often offline, we would use Couch.

- mobile
  - Couch is better as a mobile embedded database on phones, primarily because of its online/offline replication/sync capabilities.
  - we like Mongo server-side; one reason is its geospatial indexes.
  - if we had very high performance requirements we would use Mongo. For example, web site user profile object storage and caching of data from other sources.
  - for a problem with very high update rates, we would use Mongo as it is good at that because of its "update-in-place" design. For example see updating real time analytics counters
  - in contrast to the above, couch is better when lots of snapshotting is a requirement because of its MVCC design.

Generally, we find MongoDB to be a very good fit for building web infrastructure.

**Licensing**

- Database:
  - Free Software Foundation's GNU AGPL v3.0.
  - Commercial licenses are also available from 10gen, including free evaluation licenses.
- Drivers:
  - mongoddb.org supported drivers: Apache License v2.0.
  - Third parties have created drivers too; licenses will vary there.
- Documentation: Creative Commons.

The goal of the server license is to require that enhancements to MongoDB be released to the community. Traditional GPL often does not achieve this anymore as a huge amount of software runs in the cloud. For example, Google has no obligation to release their improvements to the MySQL kernel – if they do they are being nice.

To make the above practical, we promise that your client application which uses the database is a separate work. To facilitate this, the mongoddb.org supported drivers (the part you link with your application) are released under Apache license, which is copyleft free. Note: if you would like a signed letter asserting the above promise please contact us.

If the above isn't enough to satisfy your organization's vast legal department (some will not approve GPL in any form), please contact us – commercial licenses are available including free evaluation licenses. We will try hard to make the situation work for everyone.

**International Docs**

Most documentation for MongoDB is currently written in English. We are looking for volunteers to contribute documentation in other languages. If you're interested in contributing to documentation in another language please email "docs at 10gen.com".

**Language Homepages**

- Deutsch
- Español
- Français
- Italiano
- Português
- Svenska

**Alerts**

This page lists critical alerts and advisories for MongoDB. This page is a work in progress and will be enhanced over time.

See http://jira.mongodb.org/ for a comprehensive list of bugs and feature requests.

**Data Integrity Related**

- Documents may be missing on a replication secondary after initial sync if a high number of updates occur during the sync that move the document (i.e., the documents are growing).
When stepping down a replica set primary, the primary's connection to clients is not automatically closed in 2.0.1. This means that if the primary steps down while an application is issuing fire-and-forget write, the application won't necessarily fail over until it issues a query. Applications that only issue safe writes are not affected by this. The issue is fixed in 2.0.2. See https://jira.mongodb.org/browse/SERVER-4405 for details.

Security Related

- Limit access of __system when running --auth without replica sets.
  - https://jira.mongodb.org/browse/SERVER-3666 Fixed: 1.8.4
